Abstract
The synthesis of an air- and thermally stable organonickel(II) complex possessing two $\text{C}_{\text{sp}3}$-$\text{Ni(II)}$ bonds is reported. The NMR spectral data suggest that the carbanionic center in the complex carries a larger negative charge and reduced structural ring strain than the related Pd(II) and Pt(II) analogs.

Keywords: Carbon–metal bond, organometallic, bipyridine, Pd(II)-complex, Pt(II)-complex, Ni(II)-complex

Introduction
We have been interested in the synthesis of stable organo-Pd(II) complexes possessing $\text{cis}$, $\text{bis}$-$\text{C}_{\text{sp}3}$-metal bonds as potential anti-tumor agents and catalysts. This series has subsequently been expanded to include the corresponding platinum(II) counterparts. The similarities and differences between these complexes have led us to investigate the related Ni(II) members in order to determine the structural and chemical relationships within this triad family. Few meaningful series of organometallic complexes involving a complete triad have been reported, thus, this nickel complex would afford insight into potential relationships. To this end, we report herein the synthesis of the air- and thermally stable organonickel(II) complex $3a$ containing two $\text{cis}$-$\text{C}_{\text{sp}3}$-Ni bonds, which are in contrast to the more common $\text{sp}^2$-hybrids. These stable complexes also possess $\beta$-hydrogens, which when present, usually lead to facile elimination reactions. Lastly, in general, organonickel(II) complexes are not noted for their thermal stability; in fact, the main interest relates to their ability to generate organic radicals, an artifact of their inherent instability.
Results and Discussion

The insolubility of most nickel salts in organic solvents prevents the use of our normal procedure for Pd(II)-complex formation, since the one-pot mixture of ligand-soluble metal salt (e.g., NiCl₂·6H₂O or NiBr₂), and K₂CO₃ in MeCN led to the quantitative precipitation of nickel carbonate. The methodology used in the synthesis of Pt(II) complexes seemed more amenable for entry into the organonickel series. Addition of anhydrous NiBr₂ to bipyridine ligand I (Scheme 1) in either CH₂Cl₂ of CHCl₃ afforded (ca. 60 %) the initial N,N-complex 2a, which could also be synthesized by refluxing a solution of anhydrous NiBr₂ and I in dry THF under argon for 18 h. This homogeneous procedure was cleaner and the work-up was easier than for our more traditional heterogeneous method.

An interesting feature of complex 2a is that the NMR spectra are nearly superimposable with that of the free ligand; however, its elemental analysis, visible purple chromophore, and X-ray crystallographic data support the assignment. Although its ¹H NMR spectrum was identical to that of the ligand, its ¹³C NMR showed a –2.9 ppm shift for C-2 while the remaining shift differences were in the –1.4 to –0.8 ppm range. The rationale for the minor shifts in the NMR data became apparent on the basis of its X-ray analysis, in which the N,N-coordinated complex is tetrahedral; thus along with the lack of steric interactions, present in the square planar Pt(II) and Pd(II) analogs, the electronics of Ni(II) in this geometry are very comparable to Zn(II) in that it is effectively neutral.

Despite the tetrahedral geometry of 2a in the solid state, sufficient distortion must occur due to the electron pairing in solution, since no evidence for paramagnetism was found in the NMR data. The geometry in 2a is typical of such complexes, in which Ni-N bond lengths of 1.981(4) and 2.004(4)Å and Ni-Br bond lengths of 2.336(1) and 2.322(1)Å are observed along with an 85° dihedral angle between the NiN₂ plane and the NiBr₂ planes. The Ni lies 0.154Å out of the least-squares plane of the bipyridine sub-unit and the two Br atoms lie 1.475 and 2.417Å above and below the plane, respectively. A more detailed presentation of the structural features of 2a appears elsewhere.

Scheme 1. For Ni cyclometallation: (a) anhydrous NiBr₂, CH₂Cl₂, 25 ºC; (b) tert-BuOK, anhydrous THF, 0 ºC.

Despite the tetrahedral geometry of 2a in the solid state, sufficient distortion must occur due to the electron pairing in solution, since no evidence for paramagnetism was found in the NMR data. The geometry in 2a is typical of such complexes, in which Ni-N bond lengths of 1.981(4) and 2.004(4)Å and Ni-Br bond lengths of 2.336(1) and 2.322(1)Å are observed along with an 85° dihedral angle between the NiN₂ plane and the NiBr₂ planes. The Ni lies 0.154Å out of the least-squares plane of the bipyridine sub-unit and the two Br atoms lie 1.475 and 2.417Å above and below the plane, respectively. A more detailed presentation of the structural features of 2a appears elsewhere.
Cyclometallation of 2a was difficult due to the ease of Ni(II) extraction. Use of various carbonates (e.g., K or Cs) in different solvents led to the same result, quantitative recovery of the free ligand and the formation of NiCO₃. The first success was attained using 50% NaH and 2a in anhydrous THF at reflux for 4-6 h under argon; however, the yields of the desired product 3a were variable and the work-ups difficult. Thus, treatment of 2a with a slight excess (1.05 equiv.) of tert-BuOK in dry THF at 0 °C under argon caused an immediate color change (light purple to yellow) and the formation of the stable yellow microcrystalline 3a, whose ¹H NMR spectrum paralleled that of the Pd(II) and Pt(II) analogs, 3b and 3c, respectively.

In the ¹H NMR data (Table 1), H-5 showed a slight upfield shift (+0.06 ppm), while H-3 shifted downfield (-0.90 ppm) owing to conformational changes from the anti (ligand) to the syn (complex), and metal coordination. A shift of +0.07 ppm for H-4 was the smallest within the series (cf.: +0.20 for 3b and +0.27 for 3c). For 3a, the alkyl portion was also supportive of cyclization, as indicated by a +0.35 ppm shift for the CH₂ moieties demonstrating that the 5·5·5-fused ring system is better suited to the smaller transition metal (i.e., Ni) when compared to the +0.52 ppm shift for 3b and 3c. The ¹³C NMR spectrum for 3a further verified the more efficient “fit” of the Ni(II) into this core since the CH₂ shift was +5.5 vs. +12.2 for 3b and +14.2 ppm for 3c. Shifts experienced with this signal have been mainly attributed to ring strain. Ligand-to-metal donation is supported by the upfield shift of H-4 in the ¹H NMR spectrum and the upfield shift (+2.6 ppm) for C-4 in the ¹³C NMR spectrum. The location of the ¹³C NMR signal (45.0 ppm) for the metallated carbon in 3a indicated an increased electron density at the carbanionic centers compared to that of 47.4 for 3b and 49.0 for 3c ppm; these results were not surprising in view of the decreased electronegativity of Ni(II) as compared to Pd(II) and Pt(II).

Due to ¹⁹⁵Pt couplings: (a) Triplet/sextet. (b) Singlet/doublet.
Complex 3a not only provides entrance into air- and thermally stable organonickel(II) complexes containing two $C_{sp3}$-Ni bonds, but also completes a series of complexes of the nickel triad, thus allowing comparisons of their respective chemical and spectral properties. The use of 3a in potential anti-tumor activity is being explored.

Experimental Section

General Procedures. Melting points were determined with an Electrothermal 9100 instrument and are uncorrected. $^1$H- and $^{13}$C- NMR spectra were recorded on a Bruker DPX250 spectrometer using CDCl$_3$, except where noted. IR spectra were recorded on an ATI Matheson Genesis FTIR spectrophotometer. Absorption spectra were measured on a Hewlett Packard 8452A Diode Array spectrophotometer in MeCN solution at 25 °C.

Dibromo[dimethyl-$\alpha,\alpha'$-bis(methoxycarbonyl)(2,2'$'$-dipyridine)-6,6'$'$-di(propionate)]nickel(II) (2a). A solution of the bipyridinyl ligand 5 in anhydrous CH$_2$Cl$_2$ was slurried with anhydrous NiBr$_2$ (1.05 equiv.) at 25 °C for at least 24 h. Filtration of the purplish-pink slurry, followed by concentration *in vacuo* gave the crude $N,N$-complex, which was chromatographed (SiO$_2$) eluting with CH$_2$Cl$_2$, then 1% MeOH/CH$_2$Cl$_2$, followed by recrystallization (C$_6$H$_6$) to afford (60%) 2a, as purple crystals: $^{29}$ m.p. 183–185 °C (dec.); for NMR data, see Table. Anal. Calcd. for C$_{22}$H$_{24}$N$_2$O$_8$NiBr$_2$·0.5 H$_2$O: C, 42.77; H, 3.88; N, 3.99. Found: C, 42.65; H, 4.01; N, 3.89.

[2,2'$'$-Dipyridine]-6,6'$'$-diyl-[1,1'-bis(methoxycarbonyl)-2,1-ethanediyl]-C, C', N, N'-nickel(II) (3a). An anhydrous THF solution of complex 2a was treated with tert-BuOK (2.05 eq.) at 0 °C under argon for 3 h. The resultant yellow solution was concentrated *in vacuo* then chromatographed (SiO$_2$), eluting with 10% MeOH/CH$_2$Cl$_2$ to give (83%) 3a, as yellow microcrystals: m.p. 137–140 °C (dec.); NMR data see the Table. Anal. Calcd for C$_{22}$H$_{22}$N$_2$O$_8$Ni: C, 52.73; H, 4.42; N, 5.59. Found: C, 52.75; H, 4.36; N, 5.63.
