Abstract
The results are presented of research on the catalytic interactions of 1,3-diheteracycloalkanes with diazocompounds (N₂CH₂, N₂CHCO₂Me), the influence of the nature of the catalyst and structure of the starting heterocycles on the yield and structure of products formed.

Keywords: 1,3-Diheteracycloalkanes, diazo compounds, catalysis, 1,2-anionic rearrangement, cyclopropanation, carbene insertion into the C-X bond

Introduction
In recent years, much attention has been focused on developing new regio- and stereoselective methods for the synthesis of 1,4-diheteracyclohexanes.¹⁻⁹ This is primarily due to high and various physiological activities of these heterocyclic compounds. For example, the morpholine fragment is involved as a structural element in many pharmacological drugs.¹⁰ Tagetitoxin, containing the 1,4-oxathiane fragment is an RNA polymerase inhibitor.¹¹,¹² Cyclopropanes containing the 1,3-dioxolane fragment are of interest as synthons for the synthesis of biologically active polyfunctional compounds,¹³ for example, of 5,6-methanoleukotriene A₄, which is a stable and selective inhibitor of the biosynthesis of leukotriene.¹⁴ as well as for the production of fragrance compounds for perfumery, such as (2E)-5-(2,2-dimethylcyclopropyl-3-methylpent-2-enal (citral-6,7-cyclopropane).¹⁵

One of the convenient procedures for the synthesis of 1,3-dioxane-, morpholine-, and oxathiane- derivatives is based on the intramolecular rearrangement of oxonium-, ammonium-, and sulfonium ylides, which in their turn are generated by the catalytic reactions of diazo compounds with 1,3-diheteracyclopentanes.¹²,¹⁴ The goal of the present work is to study catalytic reactions of some 1,3-diheteracycloalkanes with N₂CH₂ and N₂CHCO₂Me and determine the regio- and stereoselectivity of this reaction.
Results and Discussion

Catalytic interaction of $\text{N}_2\text{CHCO}_2\text{Me}$ with 1,3-diheteracycloalkanes. Earlier it has been shown that $\text{N}_2\text{CHCO}_2\text{Me}$ reacts with acetals of furfural on the C-O or C-C bond depending on conditions.\textsuperscript{17,18} We have studied interactions of mono-, di- and tri-substituted 1,3-dioxolane with methyl diazoacetate in the presence of BF$_3$·OEt$_2$, Cu(OTf)$_2$, CuSO$_4$, Rh$_2$(CF$_3$CO$_2$)$_4$, Rh(P(C$_6$H$_5$)$_3$)$_3$Cl, CuCl and Rh$_2$(OAc)$_4$.\textsuperscript{19} It is established that the interaction of 1,3-dioxolanes 1a-f with $\text{N}_2\text{CHCO}_2\text{Me}$ in the presence of 2 mol.% of BF$_3$·OEt$_2$ has produced the corresponding 1,4-dioxanecarboxylates 2a-f (the reaction time was 2 h). As a result of carbene introduction into the C(2)-O(1) bond of 2-mono- and 2,2-disubstituted-1,3-dioxolanes the expansion of dioxolane rings is observed (Scheme 1).

$$\begin{align*}
\text{Scheme 1}
\end{align*}$$

2,2-Disubstituted-1,3-dioxolanes are mainly formed as trans- isomers under the conditions used by us.\textsuperscript{19} The use of Cu(OTf)$_2$ or CuSO$_4$ as catalysts for carbene formation from methyl diazoacetate yields less satisfactory results. More strict conditions (70 °C) are required for carrying out the given reaction; and yet, the yield of the formed 1,4-dioxane 2a-f does not exceed 13% and the basic products are dimethyl esters of maleic and fumaric acids.

In the reactions of 3-ethyl-2-phenyl- and 2,3-diphenyl-oxazolidines with methoxycarbonylcarbene, which is generated by thermocatalytic decomposition of methyl diazoacetate in the presence of copper bronze,\textsuperscript{16} insertion occurred predominantly into the C-N bond of the oxazolidine ring to give morpholine-3-carboxylic acid esters. It was also noted\textsuperscript{16} that in the presence of Rh$_2$(OAc)$_4$ neither insertion products of carbene into the C-N bond nor into the C-O bond are formed.

In the present study, we have examined the catalytic reactions of 3-alkyl-2-phenyl-1,3-oxazolines (3a,b) and 2-phenyl-1,3-oxathiolane (3c) with $\text{N}_2\text{CHCO}_2\text{Me}$ in the presence of Rh$_2$(OAc)$_4$. The reactions of oxazolidines 3a,b with $\text{N}_2\text{CHCO}_2\text{Me}$ in dichloromethane in the presence of 0.4 mol.% of the catalyst at 40 °C produced methyl 4-alkyl-3-phenylmorpholine-2-carboxylates 4a and 4b in 50 and 46% yields, respectively (the reaction time was 2 h). In both cases, insertion of the carbene fragment into the C-O bond of the heterocycle occurs to give trans-isomers 4a,b (Scheme 2).
Scheme 2

The morpholine derivatives 4a,b are generated apparently through the attack of methoxycarbonylcarbene on the oxygen atom of oxazolidines 3a,b to form O-ylides, which undergo the Stevens rearrangement leading to ring enlargement. It should be noted that thermocatalytic decomposition of N₂CHCO₂Me (120 °C, copper bronze) with oxazolidine 1a affords a complex mixture of compounds, in which the percentage of morpholine 4a is lower than 13%.

The stereochemical compositions of compounds 4a,b were determined by analyzing the chemical shifts and spin-spin coupling constants in the ¹H NMR spectra. The ¹H NMR spectrum of compound 4a shows doublets at δ 3.36 and 3.95 (²J₂,₃ = 8.9 Hz) corresponding to the methine protons at the C(3) and C(2) atoms, respectively, of the morpholine ring. The spin-spin coupling constant is indicative of the trans arrangement of the substituents at the adjacent carbon atoms. The COLOC 2D NMR spectrum of ester 4a shows a cross-peak between the signal for the carbonyl carbon atom (δ 169.6) and a low-field signal for the methine proton at the C(2) atom (δ 3.95), which confirms that methoxycarbonylcarbene is inserted into the C(2)-O bond of oxazolidine 3a.

The reaction of 2-phenyl-1,3-oxathiolane (3c) with N₂CHCO₂Me in CH₂Cl₂ in the presence of Rh₂(OAc)₄ produced methyl 2-phenyl-1,4-oxathiane-3-carboxylate (4c) in 72% yield (Scheme 3). In this case, as opposed to the reaction of 1,3-oxazolidines, the carbene fragment is inserted into the C-S bond of the heterocycle. Oxathiane 3c being formed as a mixture of the trans- and cis-isomers in a ratio of 1.5 : 1. Earlier, it has been noted that the reaction of ethyl diazoacetate with heterocycle 3c proceeds in the presence of Cu(acac)₂ as well, but the corresponding trans- and cis-isomers of ethyl 2-phenyl-1,4-oxathiane-3-carboxylate were synthesized only in 19% yield (the isomer ratio was ~2 : 1).
To reveal the relationships between the structure of 1,3-diheteracyclopentanes and the rate of insertion of methoxycarbonylcarbene into the carbon-heteroatom bond, the reactions of compounds 1b, 3a, 3c with N$_2$CHCO$_2$Me in the presence of Rh$_2$(OAc)$_4$ were studied by the competitive reaction method (Scheme 4). The relative reactivity was determined at 40 °C by adding a solution of N$_2$CHCO$_2$Me in dichloromethane to a mixture containing dioxolane 1b and its heteroanalog 3a or 3c in a molar ratio 1b: 3a (or 3c): N$_2$CHCO$_2$Me: Rh$_2$(OAc)$_4$ = 250: 250: 100: 1.

\[4c: \ X = \text{S, } R^1 = \text{Ph, } R^2 = \text{CO}_2\text{Me} \]

Scheme 4

As expected, 2-phenyl-1,3-oxathiolane 3c showed the highest reactivity ($k_{rel}$ (3c/1b) = 9.8), whereas oxazolidine 1a appeared to be only just slightly more reactive than 1,3-dioxolane 1b ($k_{rel}$3a/1b) = 1.7) although it is characterized by the insertion of the carbene fragment into the C-O bond rather than into the C-N bond. This fact is apparently attributed to the additional replacement at the nitrogen atom, which hinders the intermediate formation of N-ylide.

Catalytic reactions of diazo esters with 1,3-dioxanes, which are the homologs of 1,3-dioxolane, remain poorly studied, although some examples of Rh-catalyzed intramolecular transformations of 1,3-dioxanes derivatives of diazo esters and diazo ketones have been reported. Therefore, catalytic interactions of 1,3-dioxanes (5a-c) with N$_2$CHCO$_2$Me in dichloromethane in the presence of 0.5 mol.% of Rh$_2$(OAc)$_4$ at 20 °C were investigated. The reaction results in 1,4-dioxepanes (6a-c) in 20, 40 and 46% yields, respectively. The individual cis- and trans-isomers of 1,4-dioxepanes 6a-c were isolated by column chromatography. It should be noted that the reaction mixture contained no product in which methoxycarbonylcarbene is inserted between the C(2) and O(3) atoms of dioxane 5b. The resulting 1,4-dioxepanes 6a,b consisted of mixtures of two stereoisomers with the cis-isomer (≥80%) being the major compound. However, dioxane 5c reacts stereospecifically to give cis-6,6-dimethyl-2-methoxycarbonyl-3-phenyl-1,4-dioxepane (6c) in 46% yield (Scheme 5).

2-Unsubstituted and alkyl-containing 1,3-dioxanes (1,3-dioxane, 1,5-dioxaspiro-[5.5]-undecane and 4-methyl-, 2,2,4-trimethyl- and 2-isopropyl-4-methyl-1,3-dioxanes) did not react with methyl diazoacetate under our conditions.
The possible mechanism of the reaction can include the generation of ylide followed by 1,2-anionic rearrangement (the Stevens rearrangement).\textsuperscript{1,20} Apparently, the O(1) atom is involved in the formation of ylide; this is confirmed by the selective formation of products of formal insertion of methoxycarbonylcarbene into O(1)-C(2) bond. Successful reaction of methyl diazoacetate with benzaldehyde derivatives correlates well with the mechanism of 1,2-anionic rearrangement.\textsuperscript{20} According to this mechanism, the migrating group in its transition state is a free radical stabilized by conjugation in its substituents, and thus the process occurs more easily.

**Catalytic interaction of N$_2$CH$_2$ and N$_2$CHCO$_2$Me with unsaturated 1,3-diheterocycloalkanes.** It has been demonstrated\textsuperscript{24} that the introduction of the oxazolidine or boronate group into unsaturated compounds leads to an increase in both the yields of cyclopropanation products compared to those obtained in reactions with unfunctionalized molecules and the regioselectivity of cyclopropanation of dienes with N$_2$CH$_2$ in the presence of Pd$_2$(OAc)$_2$. The influence of the characteristics of the acetal substituents in olefins on catalytic reactions of the latter with N$_2$CH$_2$ has not been previously examined. In the present study, we examined the influence of the nature of the acetal group and the catalyst on the catalytic cyclopropanation with diazomethane of a series of unsaturated compounds, derived from trans-crotonaldehyde (8a,d), trans-cinnamaldehyde (8b,e) and hex-5-en-2-one (8c,f) (Scheme 6).
Cyclopropanation was carried out at 5–10 °C by adding a solution of N₂CH₂ in Et₂O or CH₂Cl₂ to an unsaturated compound in the presence of a catalyst, in the molar ratio of 50: 150: 1 of olefin: N₂CH₂: catalyst, for 30 min. Investigation of cyclopropanation of dioxolane 8a with the use of Pd(OAc)₂, PdCl₂, Pd(acac)₂, CuCl₂, [CuOTf]₂·C₆H₆, Cu(acac)₂, and Cu(OTf)₂ as the catalysts demonstrated that Pd(acac)₂ and Cu(OTf)₂ are the most efficient palladium and copper catalysts, respectively, under the reaction conditions used. Cyclopropanation catalyzed by Pd(acac)₂ or Cu(OTf)₂ afforded products in 99 and 49% yields, respectively. Hence, all further reactions were carried out with the use of these two catalysts. The resulting cyclopropanes were isolated by preparative TLC and characterized by ¹H- and ¹³C- NMR spectroscopy.

Compound 8a reacts with N₂CH₂ in the presence of Pd(acac)₂ or Cu(OTf)₂ to give a complex mixture of products. By contrast, cyclic acetal 8d containing two electron-withdrawing butoxycarbonyl groups at positions 4 and 5 of the dioxolane fragment is readily subjected to cycloprotonation in the presence of Pd(acac)₂ to form dibutyl 2-(trans-2-methylcyclopropyl)-1,3-dioxolane-trans-4,5 dicarboxylate (8d). Unlike simple crotonaldehyde derivatives 8a, cinnamaldehyde derivatives react with N₂CH₂ in the presence of Pd(acac)₂ to give the corresponding cyclopropane derivatives 9b,e in high yields. Cyclopropanation of hexenone derivatives 8c,f occurs with a somewhat higher efficiency compared to hexenone and produces cyclopropanes 9c,f in 87-99% yields.

The Cu(OTf)₂ catalyst is less efficient than Pd(acac)₂ in cyclopropanation of cinnamaldehyde derivatives 8b,e or hexenone derivatives 8c,f, and these reactions give the corresponding cyclopropanes in low yields. In the reaction of unsaturated compound 8b, Cu(OTf)₂ catalyzes the acetal deprotection giving rise to the starting cinnamaldehyde, the reaction being typical only of cinnamaldehyde derivatives.

The higher efficiency of Pd compounds in the cyclopropanation of unsaturated acetals is apparently associated with intramolecular stabilization of π-olefin complexes by oxygen atoms.¹³b

The study of catalytic cyclopropanation of 1,2-disubstituted double bonds in unsaturated carbonyl compounds and their acetal (ketal) derivatives with diazomethane provided evidence for higher selectivity of cyclopropanation of the latter compared to the starting unsaturated carbonyl compounds and for the activating effect of the acetal fragments on the reactivity of the C=C bond compared to the cyclopropanation of usual 1,2-disubstituted alkenes.¹³b

The interaction of equimolar quantities of methyl diazoacetate with cyclic acetals 10a,b and 1,3-oxathiolanes 10c,d in the presence Rh₂(OAc)₄ proceeds selectively and results in products of C-X insertion 11a-c and [2,3]-sigmatropic rearrangement 12a-d (Scheme 7). The absence of cycloaddition products of methoxy carbonylcarbene to the C=C bond in the reaction mixture and arrangement of substituents in the isolated products testifies that reaction proceeds through formation of one ylide. The formation of ylides takes place by the electrophilic addition of carbenoid species generated from methyl diazoacetate to the heteroatom under the action of the catalyst. The selectivity of formation of products of Stevens rearrangement 11a-c and [2,3]-
Sigmatropic rearrangement 12a-d is defined by the influence of both electronic and steric factors of the substituents.\(^{25,26}\)

\[
\begin{align*}
\text{Scheme 7}
\end{align*}
\]

At the transition to 1,3-dioxo- and 1,3-oxathiolanes having a C=C bond in \(\gamma\)-position to a heterocyclic substituent, the regioselectivity of reactions with methyl diazoacetate is defined by the nature of the heteroatom. The reaction of 2-(but-3-enyl)-2-methyl-1,3-dioxolane 8c with \(\text{N}_2\text{CHCO}_2\text{Me}\) leads to the formation of a mixture of dimethyl esters of trans- and cis-2-[2-(2-methyl-1,3-dioxolan-2-yl)ethyl]cyclopropanecarboxylic acids 14 in a 3:2 ratio and 40% total yield. At the same time, the reaction of 2-(but-3-enyl)-2-methyl-1,3-oxathiolane 13 with \(\text{N}_2\text{CHCO}_2\text{Me}\) catalyzed by \(\text{Rh}_2(\text{OAc})_4\) is accompanied by the insertion of a methoxycarbonylmethylene fragment into the five-membered ring resulting from the Stevens rearrangement of the initially formed S-ylide to give selectively methyl 2-(but-3-enyl)-2-methyl-1,4-oxathiane-3-carboxylate 15 in 50% yield (Scheme 8).

\[
\begin{align*}
\text{Scheme 8}
\end{align*}
\]

Interaction of \(\text{N}_2\text{CHCO}_2\text{Me}\) with 2-(trans-2-phenylethynyl)- and 2-(but-3-enyl)-2-methyl-3-ethyl-1,3-oxazolidines in \(\text{CH}_2\text{Cl}_2\) leads to formation of the corresponding unsaturated carbonyl compounds by catalyzed \(\text{Rh}_2(\text{OAc})_4\) cleavage of oxazolidines.
Conclusions

Convenient methods of synthesis of morpholines, 1,4-dioxanes, 1,4-oxathianes and 1,4-dioxepanes derivatives and 1,3-dioxolanes containing cyclopropane fragments are developed. They are based on the catalytic interactions of 1,3-diheteracycloalkanes with diazomethane and methyl diazoacetate. It is shown, that 1,3-dioxolanes react with N₂CHCO₂Me in the presence of BF₃·OEt₂, Cu(OTf)₂, CuSO₄ or Rh₂(OAc)₄, leading to formation of 1,4-dioxanes, being the products of formal insertion of methoxycarbonylcarbene into the C(2)-O(1) bond. 1,4-Dioxepanes are synthesized by the interaction of N₂CHCO₂Me with 1,3-dioxanes in the presence of Rh₂(OAc)₄. Methoxycarbonylcarbene generated by the catalytic decomposition of methyl diazoacetate in the presence of Rh₂(OAc)₄, is regioselectively inserted into the C(2)-O bond of 3-alkyl-2-phenyl-1,3-oxazolidines and into the C(2)-S bond of 2-phenyl-1,3-oxathiolane. The activating effect of the acetal fragments on the reactivity of the C=C bond of unsaturated compounds in cyclopropanation with N₂CH₂ catalyzed by Cu and Pd compounds is shown. It is established, that cyclic acetals and 1,3-oxathiolanes react with methyl diazoacetate to yield the products of Stevens rearrangement and [2,3]-sigmatropic rearrangement.

Experimental Section

General Procedures. The ¹H- and ¹³C- NMR spectra were recorded on a Bruker AM-300 spectrometer (300.13 and 75.47 MHz, respectively) in CDCl₃ with SiMe₄ as the internal standard. The IR spectra were measured on a Specord M82-63 instrument in a thin layer. The mass spectra were obtained on an MX-1320 instrument; the ionizing electron energy was 70 eV; the temperature of the ionization chamber was 50-70 °C. The GLC analysis was carried out on a Chrom-5 chromatograph equipped with a flame ionization detector (with a 1200×5 mm column with 5% SE30 on Inerton N-AW DMCS (0.125-0.160 mm) using helium as the carrier gas. The TLC analysis was performed on Silufol chromatographic plates (Merck). Preparative separation was performed by column chromatography on silica gel Chemapol (60 L, 100/160 µm). Starting 1,3-diheteracycloalkanes were synthesized according to known procedures,¹⁹,²⁷ distilled under a stream of argon, and stored under an inert atmosphere over metallic sodium. The solvents (CH₂Cl₂, diethyl ether, benzene, hexane, and petroleum b.p. 40–70 °C) were purified according to standard procedures.

Reactions of 1,3-dioxolanes 1a-f with methyl diazoacetate in the presence BF₃·OEt₂ (general procedure). Methyl diazoacetate 2.5 g (25 mmol) was added with vigorous stirring at 20 °C over 1 h to a solution of 1,3-dioxolane (50 mmol) and BF₃·OEt₂ 0.07 g (0.5 mmol). The reaction mixture was additionally stirred for 1 h. The residue was dissolved in 10 mL of diethyl ether and passed through a thin layer of Al₂O₃. All products 2a-f were purified by vacuum distillation.
Methyl 3-isopropyl-1,4-dioxane-2-carboxylate (2a, 45%).\textsuperscript{19} Methyl 3-phenyl-1,4-dioxane-2-carboxylate (2b, 89%).\textsuperscript{19} Methyl 3-cyclohexyl-1,4-dioxane-2-carboxylate (2c, 30%).\textsuperscript{19} Methyl 3-(dibromomethyl)-3-phenyl-1,4-dioxane-2-carboxylate (2d, 60%).\textsuperscript{19} Methyl 3-(dichloromethyl)-3-isopropyl-1,4-dioxane-2-carboxylate (2e, 53%).\textsuperscript{19} Methyl 3-dichloromethyl-3-phenyl-1,4-dioxane-2-carboxylate (2f, 82%).\textsuperscript{19} 

Reactions of 1,3-diheteracyclopentanes 3a–c with methyl diazoacetate. General procedure. A solution of methyl diazoacetate (1.10 g, 11 mmol) in CH$_2$Cl$_2$ (15 mL) was added to a stirred solution of 1,3-diheteracyclopentane (13 mmol) and Rh$_2$(OAc)$_4$ (24 mg, 0.054 mmol) in CH$_2$Cl$_2$ (35 mL) at 40 °C for 1 h. The reaction mixture was additionally stirred for 1 h. Then the solvent was removed, and the residue was dissolved in Et$_2$O (10 mL). The solution was passed through a thin layer of Al$_2$O$_3$, the solvent was removed \textit{in vacuo}, and the residue was distilled off or chromatographed on silica gel.

Methyl \textit{trans}-4-ethylmorpholine-3-phenyl-2-carboxylate (4a, 50%).\textsuperscript{27a} Methyl 4-isobutyl-3-phenylmorpholine-2-carboxylate (4b, 46%).\textsuperscript{27a} Methyl 2-phenyl-1,4-oxathiane-3-carboxylate (4c 72%).\textsuperscript{27a} 

Competitive reactions of methyl diazoacetate with 2-phenyl-1,3-dioxolane (1b) and 1,3-diheteracyclopentanes 3a and 3c. A solution of methyl diazoacetate (1 g, 10 mmol) in CH$_2$Cl$_2$ (15 mL; molar ratio 1b : 3a (or 3c): N$_2$CHCO$_2$Me: Rh$_2$(OAc)$_4$ = 250: 250: 100: 1) was added to a stirred solution of dioxolane 1b (3.77 g, 25 mmol), 1,3-oxazolidine 3a (or 3c) (25 mmol), and Rh$_2$(OAc)$_4$ (44.2 mg, 0.1 mmol) in CH$_2$Cl$_2$ (50 mL) at 40 °C for 2 h. After completion of the reaction, samples were withdrawn three times and GLC analysis was performed. The relative reactivities of 1,3-diheteracyclopentanes were calculated by the equation $k_{rel} = aS_1/S_0$, where $S_0$ is the peak area of methyl 3-phenyl-1,4-dioxane-2-carboxylate (2b), $S_1$ is the peak area of the insertion product of methoxycarbonylcarbene into the C-heteroatom bond of 1,3-diheteracyclopentane 3a or 3b, and $a$ is the calibration factor ($a = 1.14$ and 1.08 for 4a and 4c, respectively). Based on the experimental data, $k_{rel}(3c/1b) = 9.8$ and $k_{rel}(3a/1b) = 1.7.\textsuperscript{27a}$

Reactions of 1,3-dioxanes with methyl diazoacetate. General procedure. Methyl diazoacetate (1.12 g, 11.2 mmol) in 3 mL of CH$_2$Cl$_2$ was added with vigorous stirring at 20 °C over 1 h to a solution of 1,3-dioxane (15 mmol) and Rh$_2$(OAc)$_4$ (0.03 g, 0.056 mmol) in 10 mL of CH$_2$Cl$_2$. One hour after, methylene chloride was evaporated, and the residue was dissolved in 10 mL of diethyl ether and passed through a thin layer of Al$_2$O$_3$. The solvent was removed, and the residue was chromatographed on silica gel in hexane-AcOEt with a gradient from 5 to 100% of AcOEt.

2-Methoxycarbonyl-3-phenyl-1,4-dioxepane (6a, 20%).\textsuperscript{27b} 5-Methyl-2-methoxy-carbonyl-3-phenyl-1,4-dioxepane (6b, 40%).\textsuperscript{27b} cis-6,6-Dimethyl-2-methoxycarbonyl-3-phenyl-1,4-dioxepane (6c, 46%).\textsuperscript{27b}
Cyclopropanation of unsaturated 1,3-dioxolanes. General procedure. A 0.45 M \( \text{N}_2\text{CH}_2 \) solution in \( \text{Et}_2\text{O} \) (45 mL) was added with stirring to a solution of 1,3-dioxolane (7.0 mmol) and \( \text{Pd(acac)}_2 \) (0.042 g, 0.14 mmol) in \( \text{Et}_2\text{O} \) (20 mL) (or \( \text{Cu(OTf)}_2 \) (0.051 g, 0.14 mmol) in \( \text{CH}_2\text{Cl}_2 \) (20 mL)) at 5-10 °C for 30 min. The reaction mixture was additionally stirred for 30-40 min and passed through a thin layer of \( \text{Al}_2\text{O}_3 \). The solvent was removed in low vacuum. The residue was distilled or chromatographed on SiO\(_2\).

2-(trans-2-Phenylcyclopropyl)-1,3-dioxolane (9b, 98%).

2-(Cyclopropylethyl)-2-methyl-1,3-dioxolane (9c, 87%).

Dibutyl 2-(trans-2-methylcyclopropyl)-1,3-dioxolane-trans-4,5-dicarboxylate (9d, 95%).

Dibutyl 2-(trans-2-phenylcyclopropyl)-1,3-dioxolane-trans-4,5-dicarboxylate (9e, 99%).

Dibutyl 2-(2-cyclopropylethyl)-2-methyl-1,3-dioxolane-trans-4,5-dicarboxylate (9f, 99%).

Catalytic reaction of 2-alkenyl-1,3-diheteracyclopentanes with methyl diazoacetate. General procedure. Methyl diazoacetate (0.7 g, 7.0 mmol) in 20 mL of \( \text{CH}_2\text{Cl}_2 \) was added to a solution of 7.0 mmol of an unsaturated compound (10a-d, 8c, 13) and 0.07 mmol of \( \text{Rh}_2(\text{OAc})_4 \) in 10 mL of the solvent over 1 h and the mixture was stirred additionally for 1–1.5 h with heating. The solvent was removed, the residue was dissolved in 10 mL of diethyl ether and passed through a thin layer of \( \text{Al}_2\text{O}_3 \), the solvent was removed under slightly reduced pressure, and the residue was distilled in vacuum or chromatographed on SiO\(_2\).

Methyl 3-(trans-prop-1-enyl)-1,4-dioxane-2-carboxylate (11a, 32%).

Methyl 3-(trans-2-phenylvinyl)-1,4-dioxane-2-carboxylate (11b, 47%).

Methyl 3-(trans-prop-1-enyl)-1,4-oxathiane-2-carboxylate (11c, 8%).

Methyl 6-methyl-2,3,5,6-tetrahydro-1,4-dioxocyn-5-carboxylate (12a, 55%).

Methyl 6-phenyl-2,3,5,6-tetrahydro-1,4-dioxocyn-5-carboxylate (12b, 23%).

Methyl 6-methyl-2,3,5,6-tetrahydro-1,4-oxathiocyn-5-carboxylate (12c, 10%).

Methyl 6-phenyl-2,3,5,6-tetrahydro-1,4-oxathiocyn-5-carboxylate (12d, 10%).

Methyl 2-[2-(2-methyl-1,3-dioxolan-2-yl)ethyl]-cyclopropanecarboxylate (14, 87%).

Methyl 2-(but-3-enyl)-2-methyl-1,4-oxathiane-3-carboxylate (15, 50%).
