Abstract
ω-Phenylenediamines (OPDA) undergo smooth condensation with 4,6-di-O-benzyl- or 4,6-di-O-acetyl- or 4,6-di-O-ethyl-2,3-dideoxy-aldehydo-D-erythro-trans-hex-2-enose derived from D-glucal in the presence of 2 mol% of InCl₃ under mild conditions to afford a new class of 1,5-benzodiazepines in good yields.

Keywords: vic-Diamines, α,β-unsaturated-δ-hydroxyaldehyde, diazepines

Introduction

Benzodiazepines have recently received great importance because of their wide range of therapeutic and pharmacological properties. Many members of diazepine family are nowadays widely used as anticonvulsant, antianxiety, analgesic, sedative, antidepressive, and hypnotic agents.¹,² Benzodiazepine derivatives also find commercial use as dyes for acrylic fibers³ and as anti-inflammatory agents.⁴ In addition, 1,5-benzodiazepines are key intermediates for the synthesis of various fused ring compounds such as triazolo-, oxadiazolo-, oxazino-, or furano-benzodiazepines.⁵ As a result, various methods have been developed for the synthesis of 1,5-benzodiazepines.⁶,⁷ Due to their wide range of biological, industrial and synthetic applications, the development of mild and efficient protocols continues to be a challenging endeavor in synthetic organic chemistry. In recent years, indium chloride has evolved as mild and water-tolerant Lewis acid imparting high regio-, stereo- and chemoselectivity in various organic transformations.⁸ Compared to conventional Lewis acids, indium trichloride in particular has advantages of low catalyst loading, moisture stability and catalyst recycling. However, there have been no reports on the synthesis of diazepines from α,β-unsaturated sugar aldehyde and ω-phenylenediamines.
Results and Discussion

In this article, we describe a novel and rapid approach for the synthesis of 1,5-benzodiazepines from o-phenylenediamines and 4,6-di-O-substituted-2,3-dideoxy-aldehydo-D-erythro-trans-hex-2-enose using indium(III)chloride as a catalyst. Accordingly, treatment of o-phenylenediamine 1 with 4,6-di-O-benzyl-2,3-dideoxy-aldehydo-D-erythro-trans-hex-2-enose 2 in the presence of 2 mol% of InCl3 in ethanol at room temperature afforded 1,5-benzodiazepine 3a in 85% yield (Scheme 1).

Scheme 1

The structure of the product 3a was established by using various solution NMR experiments like DQFCOSY, NOESY and HSQC. The HSQC spectrum showed that the presence of four CH2 and eight CH’s in the product 3a.

Figure 1. Schematic diagram with long range nOes of 3a.

In a similar manner, various substituted o-phenylenediamines such as 4-methyl-, 4,5-dimethyl-, reacted rapidly with 4,6-di-O-benzyl-2,3-dideoxy-aldehydo-D-erythro-trans-hex-2-enose to give the corresponding benzodiazepine derivatives (entries 1a-c Table 1). Other substrates such as 4,6-di-O-ethyl- and 4,6-di-O-acetyl-2,3-dideoxy-aldehydo-D-erythro-trans-hex-2-enose gave the respective substituted 1,5-benzodiazepines in good yields under similar conditions (entries d-g, Table 1). All the products were characterized by 1H, 13C NMR, IR, and mass spectral analysis. The probable mechanism seems to be addition of amine to the unsaturated position of conjugated aldehyde, which is activated by indium trichloride. Thus the
initially formed Michael adduct may undergo cyclization with another amino group leading to the formation of diazepine (Scheme 2).

Scheme 2

Among various acid catalysts such as CeCl₃.7H₂O, YbCl₃, YCl₃, and BiCl₃ tested, indium trichloride was found to give the best results in terms of reaction rates and conversion. Further, we have carried out the experiments using various solvents such as water, ethanol, ionic liquid [bmim]BF₄, acetonitrile and tetrahydrofuran. As a solvent, ethanol appeared to give the best results. The scope and generality of this process was illustrated with respect to various substituted diamines and unsaturated sugar aldehydes and the results are summarized in Table 1.

Conclusions

In summary, we have developed a mild, rapid and efficient method for the synthesis pure 1,5-benzodiazepines through the condensation of sugar derived α,β-unsaturated-δ-hydroxyaldehydes with o-phenylenediamines using indium trichloride as the catalyst. The use of commercially available indium trichloride makes this method quite simple, more convenient and practical. It is entirely a novel protocol for the preparation of benzodiazepines in a single-step operation.

Experimental Section

General Procedures. IR spectra were recorded with a Perkin Elmer FTIR spectrophotometer. ¹H NMR spectra were carried out using a Bruker Avance 300, Varian Unity 400 and Varian Unity 500MHz spectrophotometer using TMS as an internal standard in CDCl₃. Mass spectra were recorded on Micro mass VG Autospec M for FABMS mass spectrometers. Melting points for all the compounds were recorded on Electrothermal-9100 instrument. The progress of all the reactions was monitored by thin-layer chromatography (TLC) using glass plates precoated with silica gel 60F₂₅₄ to a thickness of 0.25mm (Merck). Column chromatography was conducted by elution of columns with silica gel 60-120 mesh using ethyl acetate and hexane as eluents.
General synthetic procedure

A mixture of o-phenylenediamine (1 mmol), α,β-unsaturated-δ-hydroxyaldehyde (1 mmol) and indium trichloride (0.02 mmol) in ethanol (10 mL) was stirred at room temperature for the appropriate time (Table 1). After completion of the reaction, as indicated by TLC, the reaction mixture was diluted with water and extracted by ethyl acetate (3x 10 mL). The combined organic extracts were dried over anhydrous Na₂SO₄, concentrated in vacuo and the resulting product was directly charged on small silica gel column and eluted with a mixture of ethyl acetate-hexane (1:9) to afford benzodiazepine.
