1. Introduction

Amines are important building blocks in the synthesis of various important organic compounds such as pharmaceuticals, agrochemicals, polymers, dyes, xerographic and photographic materials.¹⁻⁵ Therefore, development of new synthetic methods for amines has attracted the attention of many researchers.⁶⁻¹¹ Among modern amination methods, electrophilic amination of an easily available organometallic reagent has been found to be a viable alternative method and continues to be an active area for research in synthetic organic chemistry.¹²⁻¹⁶

To date various type of aminating reagents have been used in the electrophilic amination of organomagnesium, -zinc, -copper, and -lithium reagents for the introduction of free or protected amino moieties, such as haloamines, substituted hydroxylamines, imines, oxaziridines, oximes, diazonium salts, azodicarboxylates, azides, and metal amides. This review covers the literature published in the last twenty years in detail. In addition, older literature has been mentioned briefly.

2. Electrophilic Amination of Organomagnesium Reagents

Haloamines were one of the earliest aminating reagent class used for the amination of organomagnesium reagents.¹⁷⁻²² But, reaction of Grignard reagents with haloamines resulted in low yields because of the formation of other amines and ammonia as byproducts with expected amines.²³⁻²⁵ Therefore, haloamines have not received much attention as aminating reagents in the amination of Grignard reagents.

Recently, two successful procedures for the preparation of tertiary amines by electrophilic amination of Grignard reagents with *N*-chloroamines have been published. One of them was described by Sinha and Knochel.²⁶ They treated functionalized arylmagnesium reagents, which were prepared by a Br-Mg or I-Mg exchange by the reaction of ArBr or ArI with *i*-PrMgCl.LiCl, with benzyl-*N*-chloroamines at -45 °C to synthesize polyfunctional tertiary amines in good yields (Scheme 1). They also prepared a chiral tertiary amine from the corresponding chiral *N*-chloroamine with retention of chirality applying this procedure, but the yield was low (34%). Amination of 3-pyridylmagnesium chloride also gave a low yield (27%).

$$R^{1} = H, Me$$

$$R^{2} = Me, Et, n-Hex$$

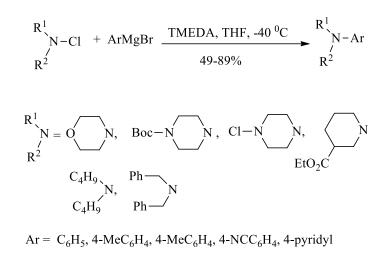

$$Ar^{1} = C_{6}H_{5}, 4-MeO_{2}CC_{6}H_{4}, 2-EtO_{2}CC_{6}H_{4}, 4-NCC_{6}H_{4},$$

$$3-NCC_{6}H_{4}, 4-IC_{6}H_{4}, 3-pyridyl$$

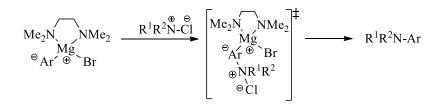

$$Ar^{2} = C_{6}H_{5}, 4-BrC_{6}H_{4}, 1-naphtyl$$

Scheme 1

Another methodology for the amination of organomagnesium compounds with *N*-chloroamines has been published in 2010 by Hatakeyama and co-workers.²⁷ In this procedure, tertiary amines were prepared by the reaction of aryl- and heteroarylmagnesium bromides with various *N*-chloroamines at -40 °C in the presence of TMEDA (Scheme 2).

It is observed that the amination reaction was unsuccessful in the absence of TMEDA or in the presence of other additives, such as TMPDA, DABCO, HMTA, PMDTA and DME. The success of the amination reaction in the presence of TMEDA was attributed to the formation of a transition state which can be stabilized by electrostatic interaction between the negatively charged chloride atom of *N*-chloramine and the magnesium atom (Scheme 3).

Scheme 3

The amination of Grignard reagents with methoxyamine was first shown by Schverdina and Kotscheschkow.^{28,29} They obtained alkyl and arylamines in good to high yields at -15 °C. Then methoxyamine was used by several research groups for the electrophilic amination of various organomagnesium compounds.³⁰⁻³² Reaction of alkylmagnesium reagents with LiNHOCH₃ was found to be unsuccessful.^{33,34}

Preparation of aniline by the electrophilic amination of phenylmagnesium bromide using *O*-phenylhydroxylamine as aminating reagent was achieved in high yield.³⁵

Some *N*,*N*-dialkyl-*O*-sulfonylhydroxylamines were reacted with organomagnesium reagents to prepare tertiary amines. But the yields of expected amines were not high.³⁶ Reaction of 1-alkynylmagnesium bromides with *N*,*N*-dimethyl-*O*-(methylsulfonyl)hydroxylamine (Me₂NOSO₂Me) was unsuccessful.³⁷

Recently, Erdik and Ateş described a Barbier-Grignard-type amination procedure for organomagnesium reagents with N,N-dimethyl-O-(mesitylenesulfonyl)hydroxylamine.³⁸ Synthesis of some N,N-dimethylanilines with high yields has succeeded (Scheme 4) but amination of *cyclo*-alkyl-, allyl-, and benzylmagnesium reagents failed.

ArBr + Mg + Me₂NOSO₂Mes
$$\xrightarrow{1. \text{ THF, r.t., 2 h.}}$$
 Me₂NAr
Ar = C₆H₅, 4-MeC₆H₄, 3-MeC₆H₄, 2-MeC₆H₄, 4-MeOC₆H₄, 3-MeOC₆H₄
Me₂NAr, yields = 60-83%

Scheme 4

Most *O*-acylhydroxylamines are not stable at room temperature because of their tendency to isomerize to hydroxamic acids. Therefore, they have not been used so much in the electrophilic amination of carbanions. Copper-II catalyzed reaction of various *N*,*N*-dialkyl-*O*-benzoylhydroxylamines with organomagnesium reagents have been shown by Champbell and Johnson.³⁹ RMgX was added slowly (0.15 mmol/min.) to the mixture of aminating reagent and copper catalyst in THF at room temperature. Tertiary amines were obtained in low to high yields (Scheme 5). But synthesis of secondary amines and *N*-phenylindole under these reaction conditions failed. It was observed that organomagnesium reagents attacked the C-atom of aminating reagents to form benzophenone, benzhydrol and triphenylmethanol as predominant products in the absence of copper catalysis. But aminating reagents bearing large acyl groups, such as 2,4,6-Me₃PhCO₂NEt₂, gave tertiary amines as the major product (85%).

$$R^{1}R^{2}NOBz \xrightarrow{R^{3}MgX (Slow addition)}{THF, CuCl_{2} (2.5 \text{ or } 10\%), rt} \xrightarrow{R^{1}R^{2}NR^{3}}{58-95\%}$$

$$R^{1}R^{2}N = Bn_{2}N, Et_{2}N, (allyl)_{2}N, morpholin-4-yl, 1-piperidyl$$

$$R^{3} = Et, {}^{c}Hex, {}^{t}Bu, C_{6}H_{5}, 4-FC_{6}H_{4}, 2-MeC_{6}H_{4}, 4-MeOC_{6}H_{4}, 2,4,6-Me_{3}C_{6}H_{2}$$

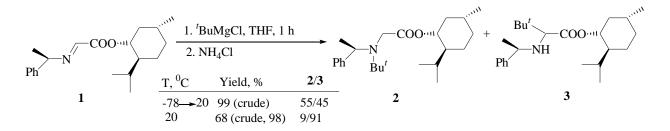

Scheme 5

O-(diphenylphosphinyl)hydroxylamine is stable at -20 °C. It was reacted with various Grignard reagents at low temperature to prepare primary amines.^{40,41} A higher yield of amine was obtained when RMgCl was used instead of RMgBr.

Organomagnesium reagents are the reagents of choice for N-alkylation reactions of α -imino esters.⁴² The first studies on this subject were published by Fiaud and Kagan.^{43,44} They observed that primary Grignard reagents showed the highest regioselection in favor of the N-alkylation.

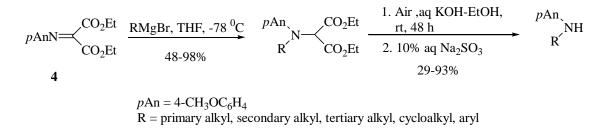

Reaction of allyl and crotyl Grignard reagents with imino ester **1** resulted in C-alkylation.^{45,46} Benzylic Grignard reagents gave only the N-alkylation product.⁴⁷

Reaction of *tert*-BuMgCl with α -imino ester 1⁴⁸ resulted in very poor regioselectivity at -78 °C (Scheme 6). When the reaction was performed at 20 °C, C-alkylated product was obtained predominantly.

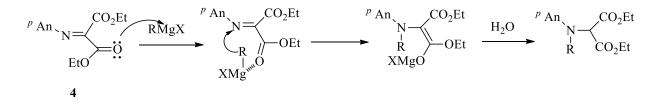

Scheme 6

Recently, 2-[N-(p-methoxyphenyl)] malonate **4** has been introduced as an efficient aminating reagent for the electrophilic amination of organomagnesium reagents (Scheme 7).^{49,50}

Scheme 7

The mechanism of this amination reaction was predicted to be as shown in Scheme 8. In the first step, organomagnesium reagent coordinates to the carbonyl group of iminomalonate 4. By this way the electron density of nitrogen atom is decreased. Then the alkyl group attacks the nitrogen atom to form the magnesium enolate. Hydrolysis of this enolate gives the desired amine.

Scheme 8

THF was found to be the most suitable solvent for the N-alkylation reaction. Iodosylbenzene and air oxygen were the most effective oxidants for the oxidation of N-alkylated products. But in the case of oxidation with air, it was necessary to use 10% aqueous Na₂SO₃ for the work-up procedure otherwise oxygen was not effective.

The highest yields were obtained with primary Grignard reagents. Cyclohexyl-, benzyl-, phenyl-, isopropyl-, and *tert*-butylmagnesium bromides gave N-alkylation in low yields at -78 °C, but in higher yields at -95 °C.

Oximes are a class of aminating reagents which have been widely used in the electrophilic amination of organomagnesium reagents. There are a limited number of works which employ aldoximes as the aminating reagent in the electrophilic amination of organomagnesium reagents.^{51,52}

Attention has been focused on the amination with ketoximes.⁵³⁻⁵⁷

Among a number of O-substituted ketoximes ($R_2C=NOX$, X = H, CH_3 , $(CH_3)_3Si$, Ts, MesSO₂) acetone *O*-(2,4,6-trimethylphenylsulfonyl)oxime **5a** was found to be a useful reagent for the amination of arylmagnesium reagents (Scheme 9, Method A).^{58,59} Treatment of phenylmagnesium bromide with **5a** in diethyl ether-toluene (1:6 by volume) at 75 °C gave aniline in 58% yield after 40 h. Addition of 10 mol % CuI or 20 mol % MgCl₂ as catalyst to the reaction mixture decreased the reaction time to 11 h and 22 h, respectively, without a significant change in the yield.

Reaction of aryl bromides with **5a** and magnesium in THF under Barbier conditions allowed preparation of arylamines almost in the same or higher yields as those obtained by the procedure described above after 3 h without the need for any catalyst (Scheme 9, Method B).⁶⁰ Arylamines were synthesized by simultaneous addition of THF solutions of the aryl bromide and **5a** to magnesium and then heating the mixture under reflux for 3 h.

Scheme 9

Narasaka and coworkers used benzophenone *O*-sulfonyloxime derivatives having electronwithdrawing groups (Scheme 10) for the electrophilic amination of alkyl, cycloalkyl and arylmagnesium reagents.⁶¹⁻⁶³ 4,4'-Bis(trifluoromethyl)benzophenone *O*-methylsulfonyloxime **6a** reacts with primary-, secondary-, tertiary- and cyclo-alkylmagnesium reagents in THF-HMPA, at 0 °C and in the presence of CuCN.2LiCl as catalyst, to furnish the corresponding amines in high yields. Furthermore, amination of 1-norbornylmagnesium chloride and 1-adamantylmagnesium bromide under these reaction conditions resulted in high yields (82 and 96%, respectively). But in the case of phenylmagnesium bromide the Würtz reaction occurred instead of an amination reaction and aniline formed only in 7% yield but mainly biphenyl in 74% yield.

n-Butylamine and 1-norbornylamine were prepared in 99% and 96% yields, respectively, using 4,4'-bis(trifluoromethyl)benzophenone *O-p*-tolylsulfonyloxime **6b** under reaction conditions of amination with **6a**. The success of the reaction of **6b** with aryl Grignard reagents in the absence of copper catalyst, depends on the solvent used in the preparation of arylmagnesium reagent. In the case of PhMgBr/THF, amination reaction resulted in 34% yield, but reaction with PhMgBr prepared in diethyl ether afforded the desired product in 62% yield.

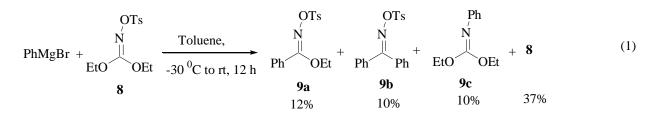

Scheme 10

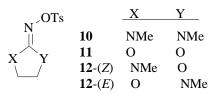

Similar observations were obtained in the reaction of arylmagnesium reagents with 3,3',5,5'-tetrakis(trifluoromethylphenyl)benzophenone *O-p*-tolylsulfonyloxime **7** and functional group containing arylamines were prepared in high yields by the use of corresponding arylmagnesium reagents prepared in diethyl ether (Scheme 10).

O-Sulfonyloximes of ureas and carbonates were screened for the electrophilic amination of organomagnesium reagents.⁶⁴ It was determined that, in the reaction of diethyl carbonate *O*-

tosyloxime **8** with phenylmagnesium bromide in toluene, the organomagnesium reagent attacked either oxime carbon or the nitrogen atom to afford a mixture of **9a-c** and **8** (Eq. 1).

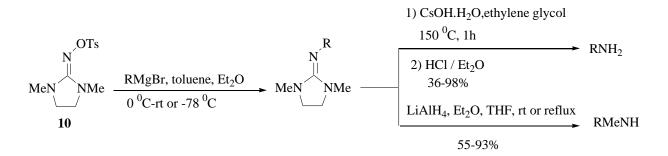

Cyclic urea and carbonate O-sulfonyloximes **10-12** (Scheme 11) were reacted with phenylmagnesium bromide and **10** was determined as the most useful aminating reagent for the amination of Grignard reagents prepared in diethyl ether. This oxime is more reactive in toluene as compared to THF. While the Z-isomer of oxime **12** gave only the N-phenylation product, the *E*-isomer gave C-phenylation reaction.

Scheme 11

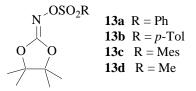

Conversion of imine, formed after amination reaction, to aniline under acidic conditions failed. It is found that it can be selectively converted into aniline in high yield by treatment with CsOH.H₂O in ethylene glycol at 150 °C for 1h or to *N*-methylaniline in high yield by the reduction with LiAlH₄ in THF at room temperature for 12 h.

Primary, secondary and tertiary (except *t*-Bu) alkylmagnesium bromides reacted with compound **10** at -78 °C, and heteroaryl and functional groups bearing arylmagnesium bromides at 0 °C to give the corresponding imines, which upon hydrolysis or reduction provide the corresponding amines or *N*-methylamines, respectively, in good to high yields (Scheme 12). But the hydrolysis and reduction of 2,6-dimethylphenylimine and 4-trifluoromethylphenylimine could not be achieved. In addition, 2-thienylimine could not be converted to the primary amine.

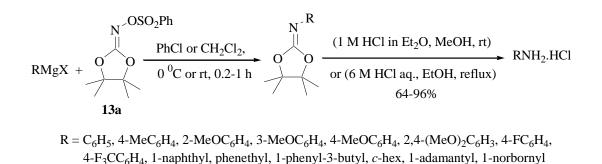

Narasaka's group screened various 1,3-dioxolan-2-one *O*-sulfonyloximes **13a-d** (Scheme 13) and introduced 4,4,5,5-tetramethyl-1,3-dioxalan-2-one *O*-phenylsulfonyloxime **13a** as a more appropriate aminating reagent for organomagnesium reagents than *O*-sulfonyloximes mentioned above.⁶⁵

Scheme 13

Compound **13a** reacted with aryl and functionalized arylmagnesium reagents prepared in Et_2O at room temperature in dichloromethane or at 0 °C in chlorobenzene to afford the corresponding arylamines in excellent yields after the hydrolysis of the resulting imines with 1 M HCl in Et_2O (Scheme 14). Amination of arylmagnesium reagents prepared in THF completed in a longer time while amination in THF was not efficient. Alkyl and cycloalkylmagnesium reagents also reacted with **13a** to supply the desired products in high yields after the hydrolysis of the resulting *N*-alkyl imines under reflux in acidic EtOH. Amination of styryl and isopropenylmagnesium reagents was achieved in excellent yields.

Organomagnesium reagents react with azides to give magnesium salts of 1,3-disubstituted triazenes which can be converted to amines by appropriate reduction or hydrolysis methods.⁶⁶⁻⁶⁹ Various azides were used for the electrophilic amination of organomagnesium reagents.

Functionalized aryl Grignard reagents, prepared in THF, give an exothermic reaction with tosyl azide. Treatment of the reaction mixture with Raney nickel and cold aqueous NaOH gives aniline derivatives in yields of up to 82%.⁷⁰

Arylmagnesium reagents, prepared in ether, can be aminated at room temperature using trimethylsilylmethyl azide in good to high yields.⁷¹ Phenylmagnesium bromide gives two parallel reactions with triphenylsilyl azide.⁷² One of these reactions is the substitution of the azide group by the phenyl group of the Grignard reagent to form tetraphenylsilane. The other reaction is the formation of the corresponding triazene salt. Decomposition of this salt at 100-120 °C, followed by the hydrolysis of the resulting *N*-(triphenylsily1)amide gives aniline.

Attack of Grignard reagents on azides, bearing electron-withdrawing groups, was assumed to be facilitated by coordination between MgBr₂ as shown in Figure 1.⁷³ Trost and Pearson showed that, in the reaction of RYCH₂N₃ (R: aryl, alkyl, Y: S, O) type heteroatom substituted azides with organomagnesium reagents, the activating influence of sulfur is higher than that of oxygen. In addition they observed that (arylthio)methyl azide was more successful than (alkylthio)methyl azide.⁷⁴

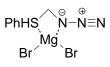

Figure 1

Addition of benzyl or butyl azide to the alkylmagnesium reagent in diethyl ether solution provides the corresponding triazene.⁶⁹

Allyl azide **14** can easily be prepared by the reaction of sodium azide with allyl bromide in water in the presence of a catalytic amount of tetrabutylammonium bromide.⁷⁵ It is used successfully as a synthem for $^{+\delta}NH_2$ in the synthesis of arylamines by the electrophilic amination

of arylmagnesium reagents (Scheme 15).⁷⁶ It is reported that azide 14 can be used without purification, but in this case the molar ratio of ArMgX: 14 must be change from 1:1 to 1:1.5.

ArNH₂, yields = 52-77%

Scheme 15

Alkyl Grignard reagents add to aryl azides to form the corresponding mono-*N*-alkylanilines in high yields (Scheme 16).⁷⁷ The method works effectively with Grignard reagent bearing both primary and secondary alkyl groups and aliphatic alkyl groups of different chain length. The formation of mono-*N*-alkylaniline as the only product (no trace of *N*,*N*-dialkylaniline) is attributed to the addition of the Grignard reagent to the azide with successive loss of N₂, followed by proton capture during aqueous workup to form mono-*N*-alkylanilines. However, reaction of aryl Grignard reagents with aryl azide afforded the corresponding diazene. This different result was thought to be due to steric factors.

$$RMgBr + Ar-N_3 \xrightarrow{1) Et_2O, rt, 0.5-1.5 h} Ar-NH-R$$

Scheme 16

Reaction of arylmagnesium reagents with benzendiazonium chloride-zinc chloride double salt, in diethyl ether, resulted in very low yields (4-29%).⁷⁸⁻⁸⁰ However, the yield was higher in THF which has stronger coordination ability.⁸¹

Arylazo tosylates which can be prepared in a two step-sequence consisting of a diazotation and tosylation of the resulting diazonium tetrafluoroborates, have been used as synthetic equivalents of the electrophilic arylamino synthon in the electrophilic amination of polyfunctional arylmagnesium reagents.⁸² Polyfunctional diarylamines can be prepared by the addition of functionalized arylmagnesium reagents to functionalized arylazo tosylates, followed by *in situ* allylation and reductive workup (Scheme 17).

Scheme 17

Amination of 3-indolylmagnesium chloride, ferrocenylmagnesium bromide and cyclopropylmagnesium bromide was achieved using this amination procedure.

Knochel and co-workers⁸³ described a procedure for the preparation of polyfunctionalized diarylamines by the reaction of arylmagnesium reagents with nitroarenes (Scheme 18). In this procedure not only organomagnesium reagent but also nitroarene can bear either electron-withdrawing or electron-donating groups. 6-Nitrobenzothiazole and 6-nitroquinoline can be arylated using this procedure to obtain the desired arylated amines in good yields.

$$Ar^{1}MgCl + Ar^{2}NO_{2} \xrightarrow{1) \text{THF, -20 }^{0}C, 2 \text{ h}} Ar^{1}NHAr^{2}$$

Scheme 18

In the first step of the mechanism (Scheme 19) addition of the first equivalent of arylmagnesium reagent, followed by the elimination of magnesium phenolate, gives nitrosobenzene. The second equivalent of arylmagnesium reagent attacks the N=O double bond of nitrosobenzene to form diarylhydroxylamine which is reduced to diarylamine (Scheme 19, path A).

In the case of nitroarenes bearing a bulky substituent next to their nitro group, the second equivalent of arylmagnesium reagent attacks the oxygen atom of the nitroso arene (Scheme 19, path B) to form the corresponding nitrene.⁸⁴ The amount of arylmagnesium reagent can be decreased from 2.3 equivalents to 1.2 equivalents by the use of nitroso arenes as starting materials (Scheme 20).⁸⁵

Scheme 20

3. Electrophilic Amination of Organozinc Reagents

Organozinc compounds are an important class of main-group organometallic reagents.⁸⁶⁻⁸⁸ The bond between carbon and zinc has a covalent character and therefore they show modest reactivity towards many electrophilic reagents. This characteristic allows them to tolerate numerous functional groups.⁸⁹

To date, only a few electrophilic amination procedures have been reported in the literature employing organozinc reagents. Coleman and coworkers reacted dialkylzinc reagents with chloroamines and obtained the desired amine as a mixture with other amines and ammonia^{21,90}

Recently, a successful study related to the preparation of tertiary amines by the electrophilic amination of diorganozinc reagents with various *N*,*N*-dialkyl-*N*-chloroamines has been published by Barker and Jarvo.⁹¹ Diphenylzinc reagent was reacted with chloroamines using bipyridine-ligated Nickel catalyst. The reaction was carried out in DMA/THF (1:2.4) mixture at 0 °C and tertiary amines were obtained in moderate to high yields (Scheme 21a). This procedure has a functional group tolerance. For example amination of substrates which have terminal alkene or amide function, using this procedure resulted in good yields of the corresponding tertiary amines.

Amination of electron-poor N,N-dialkyl-N-chloroamines such as N-chloroamides and N-chlorosuccinimide under these reaction conditions was found to be unsuccessful. Amination of arylzinc chloride at room temperature gave tertiary amine in moderate yield (55%), but at 0 °C in high yield (87%).

$$\begin{array}{c} R^{1} \\ R^{2} \\ N^{-}Cl + Ph_{2}Zn \end{array} \xrightarrow{N(cod)_{2}, 5 \text{ mol }\%, \text{ bipyridine, 10 mol }\%}_{DMA:THF (1:2.4), 0 \ ^{0}C, 4.5 \text{ h}} \\ R^{1} \\ R^{2} \\ N^{-}Cl = Bu_{2}NCl, BuMeNCl, BnMeNCl, 2-pentenylMeNCl, \\ R^{2} \\ N^{-}N \\ R^{2} \\ N^{-}Ph, \% = 90, \quad 63, \quad 49, \quad 70, \quad (86, 82, 87, 73), \quad 51, \quad 60 \end{array}$$

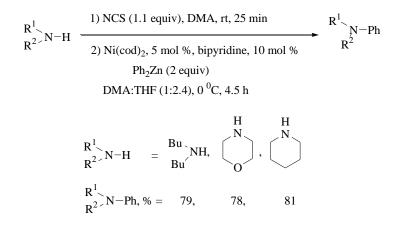

Scheme 21a

Functional group bearing diorganozinc reagents were also successfully aminated under these reaction conditions (Scheme 21b).

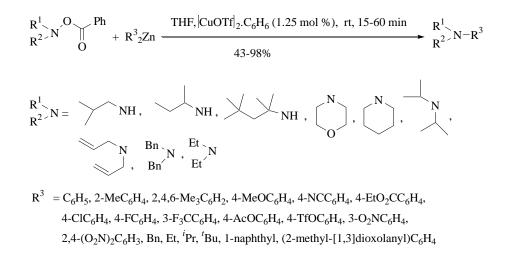

$$\begin{split} R = 4 \text{-}MeC_6H_4, \ 4 \text{-}MeOC_6H_4, \ 3,4 \text{-}(MeO)_2C_6H_3, \\ 3 \text{-}F_3CC_6H_4, \ 4 \text{-}FC_6H_4, \ 2 \text{-}thienyl \end{split}$$

Scheme 21b

Secondary amines can be converted into tertiary amines by a one-pot chlorination and arylation reaction using this procedure (Scheme 22).

N-substituted *O*-benzoyl hydroxylamines and *N*,*N*-disubstituted *O*-benzoyl hydroxylamines have been used as RNH^{+ δ} and R₂N^{+ δ} synthons, respectively, in the synthesis of secondary and tertiary amines by the copper (II)-catalyzed electrophilic amination of diorganozinc reagents,⁹²⁻⁹⁴ prepared by Li-Zn or MgBr-Zn transmetallation or by directed *ortho*-metallation, and Nickel-catalyzed electrophilic amination of organozinc halides.⁹⁵ In the amination of diorganozincs, aryl, heteroaryl, benzyl, *n*-alkyl, *sec*-alkyl, and *tert*-alkyl nucleophiles couple with aminating reagents to give the desired amines in good to high yields (Scheme 23).

Scheme 23

Copper-catalyzed amination of diorganozincs is an exothermic reaction. This warming does not affect the reaction yield in micro-scale. However when the reaction is performed on a large-scale it causes a decrease in yield (for example from 91% to 72%) if the reaction temperature is not kept at 5 °C.⁹⁶

 $[Cu(OTf)]_2.C_6H_6$, Ni(cod)₂, and Ni(cod)₂/ligand were found to be not effective in the amination of organozinc halides with *N*,*N*-disubstituted-*O*-benzoylhydroxylamines. (Ph₃P)₂NiCl₂ allowed preparation of tertiary amines in good to high yields (Scheme 24). ^{92,95}

Scheme 25

There is a need for a copper catalyst to react organozinc chlorides and diorganozincs with oximes at room temperature. Triorganozincates can react without using any catalyst, but the yield of amine is low.^{97,98} All three organozinc reagents react with **5a** in the presence of CuCN, as catalyst, to give primary amines in low to moderate yields. Primary arylamines can be obtained in high yields by the use of a dipolar aprotic cosolvent (Scheme 25).⁹⁹⁻¹⁰¹ Addition of a

P-, N-, or S-donor ligand causes a significant reduction in the quantity of copper catalysts and a remarkable increase in the yield of amine (Scheme 26).¹⁰¹

There is no need to use a copper catalyst to obtain primary arylamines in good yields, if the amination of arylzinc reagents with acetone oxime O-tosylate **5b**, in the presence of a cosolvent, is performed at 40 °C.

Scheme 27

Niwa and coworkers observed that, if the reaction of diethylzinc reagent with 2-[N-(p-methoxyphenyl)]mino]malonate **4** at -78 °C is carried out in toluene in place of THF, the

N-ethylation product can be prepared in higher yield (80% instead of 40%). In addition the reaction is completed in a shorter time.^{49,50}

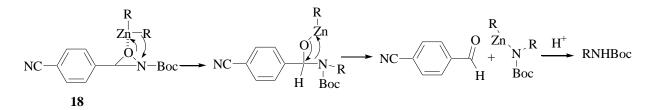

Amination of organozinc halides, diorganozincs and lithium triorganozincates with oxaziridines have been studied by Ghoraf and Vidal.¹⁰⁶ They found diorganozinc to be the most successful organozinc reagent. Amination reactions of diorganozincs with oxaridine **17** were conducted in Et₂O:hexane (1:4) at 0 °C without using any catalyst. Only *n*-alkylzincs gave high yields of Boc-protected primary amines. Amination of *sec-*, *tert-*, and cycloalkylzinc, and arylzinc reagents resulted in low yields (Scheme 28).

R = n-Bu, s-Bu, t-Bu, c-hex, cis-pinane-2-ylmethyl, C₆H₅, 4-MeOC₆H₄ Yield, % = 71, 28, 21, 40, 39, 43, 29

Scheme 28

It is proposed that the oxygen of oxaziridine **17** coordinates to the zinc atom to form the zincate complex **18**. This coordination facilitates attack of the organo group on the electrophilic nitrogen to open the oxaziridine ring (Scheme 29). Therefore, ethereal solvents, which can act as competing Lewis bases, must be avoided.

Scheme 29

Some attempts have been made to use diazonium salts for amination of organozinc reagents. Curtin and Ursprung reacted alkyl, benzyl and arylzinc chlorides with a suspension of aryldiazonium tetrafluoroborates in diethyl ether at 0 °C to afford the corresponding azo compounds in low yields. ¹⁰⁷ Attempts to carry out the reaction using a pyridine solution of aryldiazonium tetrafluoroborates resulted in poorer yields.

Diorganozinc reagents were found to react with benzenediazonium tetrafluoroborates in xylene-DMF (1:2) or in diethyl ether at 0 °C very fast and give azo compounds in high yields.¹⁰⁸

Erdik and Koçoğlu¹⁰⁹ revisited this amination reaction and showed that triarylzincates prepared by transmetallation of corresponding arylmagnesium reagents with ZnCl₂.TMEDA react with benzenediazonium tetrafluoroborate in THF at -15 °C to give the corresponding arylazo compounds in high yields (Scheme 30). Alkyl, cycloalkyl-, and benzylzincates were found to be unsuccessful. Arylazo compounds were subsequently reduced, using NaBH₄/NiCl₂.6 H₂O, and arylamines were obtained as a mixture with aniline in low to moderate yields.

$$R_{3}ZnMgBr + C_{6}H_{5}N_{2}BF_{4} \xrightarrow{1) \text{THF, -15}^{0}\text{C, 1 H}} C_{6}H_{5}N=NR$$

$$R = 4-MeC_{6}H_{4}, 4-MeOC_{6}H_{4}, 4-BrC_{6}H_{5}, n-hex, c-hex, Bn$$

$$Yield, \% = 87, 88, 72, -, -, -, -$$

Scheme 30

It is observed that triarylzincate, prepared separately, gave higher yields compared with *in situ* prepared triarylzincate, whereas *in situ* prepared arylzinc chloride was more successful than arylzinc chloride prepared separately.

Rieke and coworkers reported a procedure for the preparation of primary amines using organozinc halides and di-*tert*-butyl azodicarboxylate (DBAD) **19** in three steps.¹¹⁰ They performed the first step in high yields (Scheme 31). In this step, organozinc halide reacts with DBAD at 0 °C to afford di-*tert*-butylhydrazinodicarboxylates in moderate to high yields after hydrolysis with NaHCO₃. In the second step, the *tert*-butoxycarbonyl groups can be removed with CF₃COOH. And finally, the primary amines can be obtained after reductive cleavage of the N-N bond using H₂/Raney Ni.

4. Electrophilic Amination of Organocopper Reagents

Organocopper reagents are indispensible in the field of synthetic organic chemistry. They have been used not only for the synthesis of simple organic molecules, but also for the synthesis of various types of natural products with high chemo-, regio- and stereoselectivity.¹¹²

To date, most aminating reagents, for the electrophilic amination of mono-organocopper and cuprates were based on sp³-hybridized nitrogen species. For example, *N*,*N*-dimethyl-*O*-(methyl-sulfonyl)hydroxylamine $(Me_2NOSO_2Me)^{113}$ and *N*,*N*-dimethyl- *O*-(diphenylphosphinyl)-hydroxylamine $(Me_2NOPOPh_2)^{37}$ were used for electrophilic amination of higher order 1-alkynylcuprates, to obtain the corresponding amines in poor to high yields.

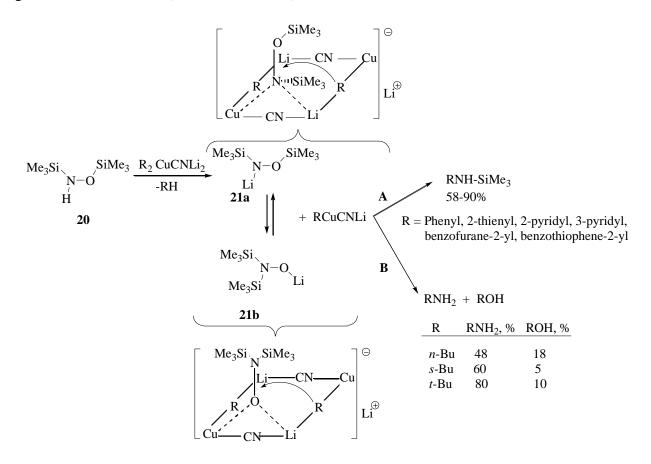

4-(Benzoyloxy)piperidine reacts with phenylcopper and diphenylcuprate to furnish aniline in good to high yields (Scheme 33).³⁹ Diphenylcuprate gives a higher yield than phenylcopper. The organometallic precursor (PhLi, PhMgBr or PhZnCl) used in the preparation of organocopper reagents does not affect the yield, but using a Li₂CuCl₃ complex instead of a CuBr.SMe₂ complex as copper source leads to an increase in the yield of aniline.

Scheme 33

Alternatively, *N*,*O*-Bis(trimethylsilyl)hydroxylamine **20**, aminated higher-order cyanocuprates to give aromatic, heteroaromatic and alkyl amines in satisfactory to high yields (Scheme 34).¹¹⁴ According to the proposed mechanism of Ricci *et. al.*, in the first step of the amination reaction, one of the R groups in R₂CuCNLi₂ abstracts one proton from the aminating reagent to give a lower-order cyanocuprate and lithium *N*-silyl-*N*-siloxamide (nitrenoid), **21a**. After the formation of **21a**, depending on the type of R group in the lithium organylcyanocuprate, nitrenoid-oxenoid (**21a-21b**) equilibrium may occur. If R is an aryl group, lithium arylcyanocuprate reacts with **21a** without allowing formation of **21b**, and gives the corresponding silylated amine (Scheme 34 path A). However, if R is an alkyl group, the **21a-21b** equilibrium may occur, and the cyanocuprate reacts with both the nitrenoid and the oxenoid to give amine and alcohol (Scheme 34 Path B).

Scheme 34

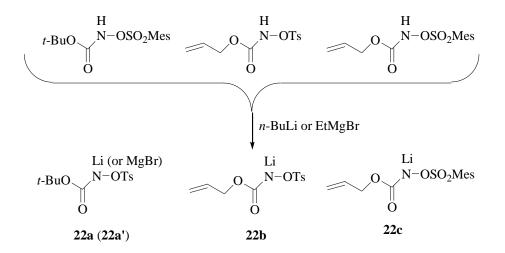

Reaction of *n*-BuPhCuCNLi₂, a mixed higher-order cyanocuprate, with **20** resulted in the formation of 50% of PhNHSiMe₃, 35% of *n*-BuNH₂, and 5% of *n*-BuOH. Ph₂CuLi₂ gave a slightly lower yield (80%) compared to the corresponding cyanocuprate (90%).

N-Alkylarylamines and *N*-alkylheteroarylamines were prepared in moderate to high yields by the electrophilic amination of higher-order cyanocuprates with *N*-alkylhydroxylamines (Scheme 35).¹¹⁵ *N*-alkyl-*O*-trimethylsilylhydroxylamines react with higher-order cyanocuprates at room temperature, whereas **20** reacts at low temperatures.

Beak and Selling³⁴ treated phenyl and *s*-butyl cuprates with methoxylamine/methyllithium at -15 °C and obtained *s*-BuNH₂ and PhNH₂ in 58 and 83% yields, respectively.

Genêt and co-workers ¹¹⁶⁻¹¹⁹ have developed new electrophilic amination reagents (Scheme 36) for the direct transfer of the N-protected moiety to a nucleophilic site. These types of reagents are useful, especially when the synthesis of sensitive primary amines, which are otherwise not stable as free bases, is needed.

Scheme 36

These reagents were found to be suitable for the electrophilic amination of arylcopper and dialkylcuprates but not for diarylcuprates and diarylcyanocuprates (Scheme 37a). The use of (MgCl)BTOC, **22a'**, supplied alkylamines in higher yields than that of LiBTOC **22a**, in the amination of dialkylcuprates. In the case of amination of PhCu, LiBTOC was more successful.

$$\begin{array}{l} \text{RM} + \text{BocN(M')OTs} & \underbrace{1) \text{ THF, -78} \, {}^{0}\text{C, 1.5 H}}_{22a, 22a'} \quad \text{RNHBoc} \\ \hline & 22a, 22a' & 2$$

Scheme 37b

Electrophilic amination of dialkylcuprates with **22a-c** was presumed to be an $S_N 2$ process in which the aminating reagent interacted with the dimeric cuprate to form an intermediate and a mechanism very similar to that proposed for the electrophilic amination of **20** with diarylcyanocuprates ¹¹⁴ was suggested.

Yamamoto and Maruoka,¹²⁰ described the preparation of secondary and tertiary amines based on the oxidative coupling of lithium diorganylcopper amides, which were generated from lithium dialkyl(or diaryl)cuprates and alkyl-, cycloalkyl-, benzyl-, or aryl- primary or secondary amines. Iwao and co-workers¹²¹ reported a procedure for the oxidative coupling reaction of *ortho*lithiated benzamides with anilido-chloro or -cyano cuprates to yield substituted *N*-aryl anthranyl amides. In both studies, five equivalents of cuprate were utilized with respect to the amine and molecular oxygen as an oxidant at -78-25 °C.

Dembech, Ricci and co-workers described the synthesis of aliphatic, aromatic, and heteroaromatic amines by oxidative coupling of lithium- and zinc-amidocyanocuprates in which one equivalent of cuprate with respect to the amine was used.^{122,123} A number of secondary and tertiary amines were synthesized by *N*-alkylation, -vinylation, -arylation, and -heteroarylation of simple primary and secondary amines using this procedure (Scheme 38). It was observed that the preparative method of the amidocuprate did not cause any major change in the yield of products.

R¹,R²,R³ = Bu,Ph,Ph; Me,Ph,PhCH₂; PhCH=CH,*i*-Pr,*i*-Pr; Ph,*i*-Pr,*i*-Pr; Ph,H,Ph; Ph,Ph,Ph; Ph,Ph,PhCH₂; 2-thienyl,Me,Ph; 2-benzofuryl,Me,Ph

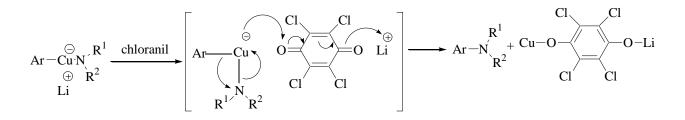

Zinc-amidocyanocuprate was found to give higher yields than lithium-amidocyanocuprate. Oxidation of zinc-amidocuprates and lithium-amidocuprates with O_2/o -dinitrobenzene and $O_2/Cu(NO_3)_2$, respectively, in place of O_2 alone, afforded higher yields.

Functional groups bearing primary, secondary, and tertiary amines were prepared by the oxidative coupling of polyfunctional aryl and heteroaryl amidocuprates (Scheme 39).^{124,125} Amidocuprates were prepared by treatment of arylcopper reagents, prepared by transmetallation of functionalized arylmagnesium reagents and CuCl₂.LiCl, with lithium amides at -50 °C for 2 h. Subsequent oxidation with 2,3,5,6-tetrachloro-1,4-benzoquinone (chloranil) at -78 to -50 °C with stirring for 12 h afforded, after purification, the desired amines.

5. Electrophilic Amination of Organolithium Reagents

Amination of organolithium reagents with haloamines is a low yielding reaction. Reaction of phenyl- and *n*-butyllithium reagents with monochloroamine, H₂NCl, in diethyl ether at -50 °C give aniline and *n*-butylamine in 33 and 39% yields, respectively.²¹ If it is reacted with monochlorodiethylamine (ClN(C₂H₅)₂) lithium phenylacetylide affords the corresponding tertiary amine in only 3% yield.²⁵

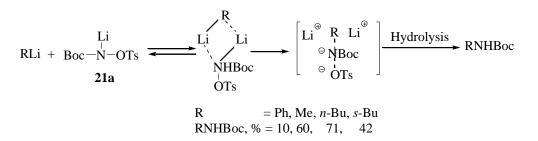

Methoxyamine **15** has been widely used for the amination of organolithium reagents.^{31,128-131} Since organolithiums may react with both protons of **15**,¹³² three equivalents of organolithium, per equivalent of methoxyamine, are used in the reactions. This difficulty can be overcome by treatment of **15** with two equivalents of methyllithium at -78 °C to form lithium methoxyamide before use. In this way one equivalent of organolithium to be aminated is sufficient and organolithiums can be aminated in higher yields (Scheme 44).^{33,34} Amination of organolithiums with alkoxyamines bearing at least one proton on nitrogen can be performed in higher yields using this method.¹³³

The mechanism of the amination reaction of alkoxyamines with organometallic reagents, which is presumed to be as a S_N2 process, has been investigated by several groups.¹³⁴⁻¹⁴³

Genêt and co-workers aminated aryl, primary and secondary alkyllithiums using lithium *t*-butyl-*N*-tosyloxycarbamate (LiBTOC), **21a**, to synthesize primary amines in their *N*-Boc protected form (Scheme 45).^{116,117,119} LiBTOC **21a** reacts with organolithium reagents according to the mechanism proposed by Beak and coworkers.¹³⁴

Scheme 45

Several *N*,*N*-dialkyl-*O*-(arylsulfony1)hydroxylamine derivatives were used in the electrophilic amination of alkyl-, alkenyl-, and aryllithiums at low temperatures.^{144,113} Reaction of 1-alkynyllithiums with *N*,*N*-dimethyl-*O*-(methylsulfonyl)hydroxylamine (Me₂NOSO₂Me) was unsuccessful.³⁷ However, *O*-(diphenylphosphinyl)hydroxylamine aminated organolithiums in moderate to good yields.^{37,41} Attempts to aminate phenyllithium with *N*,*N*-diethyl-*O*-mesityloylhydroxylamine resulted in low yields; the highest yield obtained was 50% at -30 °C.

Organolithium reagents react with azides in the same way as organomagnesium reagents to give 1,3-disubstituted triazenes. *p*-Toluenesulfonyl azide was used for introducing amino groups into *ortho*-lithiated aromatic compounds.¹⁴⁵⁻¹⁴⁷ Aryl- and heteroaryllithiums reacted with vinyl azides to give the corresponding aromatic amines in moderate to good yields after an acidic hydrolysis.¹⁴⁸ Allyl azide was found to be a useful reagent for the conversion of phenyllithium to aniline (61%) using hexane as the solvent.⁷⁶

Organolithiums cannot be aminated with (pheny1thio)methyl azide without using MgBr₂ because of the lower Lewis acidity of lithium salts.⁷³ It was reported that the reaction of (trimethylsilyl)methyl azide with aryllithiums in diethyl ether, followed by hydrolysis, generated the corresponding aromatic amines in poor yields (35-41%).¹⁴⁹ Diphenyl phosphorazidate reacts easily with aryl- and heteroaryllithiums to give the corresponding amino compounds after reduction of triazene formed with sodium bis(2-methoxyethoxy)aluminum hydride.¹⁵⁰

6. Conclusions

Electrophilic amination of organometallic reagents is an important and useful synthetic method for the preparation of aliphatic, aromatic and heteroaromatic amines and is continuing to gain the attentions of chemists. Publications on the results of our own investigations of the electrophilic aminations of organomagnesiums, mono-organocoppers, homocuprates and heterocuprates with ketoximes are in preparation.

7. Acknowledgement

The author would like to thank the Ankara University Research Fund (BAP) for supporting his research on electrophilic amination.

Author's Biography

Tahir Daşkapan received his B.S., M.S. and Ph.D. degrees from Ankara University in 1990, 1993 and 1999, respectively. He performed research on the cyclization of organolithium reagents in W. F. Bailey's group at the University of Connecticut, USA (October 2001-August 2002) as a Scientific and Technical Research Council of Turkey (TUBITAK) fellow. He is currently a Professor of Chemistry at Ankara University, Science Faculty, Department of Chemistry-Turkey. His research interests involve reactions of organo-magnesium, -lithium, -zinc and -copper reagents.
