Abstract
We describe a new synthesis of diospongins A, its enantiomer ent-diospongin A and C-5 epimer of diospongin B from commercially available tri-O-acetyl-D-glucal, based on a copper catalyzed Michael addition of phenyllithium to the corresponding α,β-unsaturated ketone. The stereochemical course of the Michael addition was unambiguously established by X-ray crystallographic analysis.

Keywords: Diospongins, natural products, total synthesis, Michael addition, Mitsunobu reaction

Introduction
Diospongins A (1) and B (2) are a novel class of cyclic 1,7-diarylheptanoid natural products (Figure 1). They were isolated in 2004 by S. Kadota and co-workers, from the rhizomes of Dioscorea spongiosa.1 While diospongin A (1) did not show any activity, diospongin B (2) exhibited a potent inhibitory activity on bone resorption induced by parathyroid hormone in a bone organ culture system and hence can be regarded as a lead compound for the development of antiosteoporotic drugs.1
Because of their biological activities, diospongins have attracted much interest in the synthetic community. Since the first asymmetric total synthesis of diospongins A and B carried out in 2006 by Jennings and co-workers, several total syntheses of 1 and 2 and their enantiomers have been developed.

Results and Discussion

As part of our ongoing program focusing on the use of readily available chiral substrate tri-O-acetyl-D-glucal (5) for the synthesis of natural products, we wish now to report the synthesis of diospongin A, ent-diospongin A and C-5 epimer of diospongin B, using this compound. Our retrosynthetic basis is outlined in Scheme 1.

Scheme 1. Retrosynthetic analysis for diastereoisomers of diospongin B.

We anticipated that a Michael addition with diphenylcuprate on enone 6 would give diastereoisomers 8 and 9, precursors of target compounds 7. Accordingly, compound 10 was prepared in 2 steps from 5 in 91% yield, following the procedure described by Mori and Hayashi (Scheme 2).
PDC oxidation of 10 afforded α,β-unsaturated ketone 6 in 97% yield which underwent copper catalyzed Michael addition of PhLi, giving a separable mixture of diastereomeric ketones 8 and 9 in a 1:1.2 ratio.

The structures of 8 and 9 were unambiguously established by X-ray crystallographic analysis of 9²⁷ (Figure 2).

**Figure 2.** X-ray crystal structure (ORTEP) of ketone 9.
We anticipated that stereoselective reduction of ketones 8 and 9 followed by side chain elaboration would lead to ent-diospongin A, in the case of ketone 8 and to diospongin B in the case of ketone 9. Accordingly, ent-diospongin A was prepared as shown in Scheme 3.

L-Selectride reduction of ketone 8 afforded stereoselectively 90% yield of alcohol 11 which was protected as MOM ether to give 12 in 90% yield. Removal of the silyl protecting group of compound 12 afforded the diol 13 (96%). The primary hydroxyl group of 13 was selectively protected giving almost quantitatively alcohol 14. Radical deoxygenation 28 of alcohol 14 led to tert-butyldimethylsilylether 16 in 72% overall yield. Removal of the TBS protecting group of 16 afforded alcohol 17 in 85% yield. Alcohol 17 was uneventfully converted into nitrile 19 in 93% overall yield by tosylation followed by tosylate displacement with sodium cyanide. Reduction of nitrile 19 with DIBALH 29 gave an aldehyde which was subjected to a reaction with PhLi to obtain alcohol 20 in 67% overall yield. PDC oxidation of alcohol 20 afforded ketone 21 (65% yield). Removal of the MOM protecting group of 21 gave 84% yield of target ent-diospongin A.

Using a similar sequence of reactions to that used above, ketone 9 led to the synthesis of C-5-epimer of diospongin B (4) (Scheme 4).

Our intention was to synthesize diospongin B (2) from 4, by means of a Mitsunobu reaction, 30 but instead of the expected compound we got diospongin A (1). The formation of 1 from 4 can be rationalized by first inversion of C-5 configuration, a retro-Michael reaction followed by an intramolecular Michael reaction which then leads to the thermodynamically more stable diospongin 1 (Scheme 5). This type of epimerization is not unprecedented as observed by Kumaraswamy and co-workers 10 while deprotecting a TBDPS group with excess of TBAF (10 equiv).

**Conclusions**

We have developed a new synthesis of diospongin A, its enantiomer and C-5-epimer of diospongin B, from a relatively cheap starting material. To the best of our knowledge this is so
far only the second synthesis described for ent-diospongin A. Our strategy could be used to generate a library of small molecules with varying substitutions in the aromatic rings. Work is now in progress for the synthesis of such diospogin analogues with a view to their biological evaluation.

**Experimental Section**

**General.** Solvents were purified and dried by standard procedures before use. Melting points are uncorrected. $^1$H NMR and $^{13}$C NMR spectra were recorded with a Bruker ARX-400 spectrometer (400 MHz for $^1$H NMR, 100.61 MHz for $^{13}$C NMR) using TMS as internal standard (Chemical shifts in $\delta$ values, J in Hz). Flash chromatography (FC) was performed on silica gel (Merck 60, 230-400 mesh); analytical TLC was performed on plates precoated with silica gel (Merck 60 F254, 0.25mm); mass spectra (FAB, EI) were recorded using FISONs VG and electron spray ionization (ESI-MS) spectroscopy was recorded using Bruker FTMS APEXIII.

Due to some C signals overlapping the number of C signals in some spectra might be less. Also some hydroxy groups H might be missing.

The residue (42 mg, 0.160 mmol) was dissolved in THF (4 mL) and was cooled to -78°C. PhLi (0.240 mmol, 0.133 mL) was added dropwise and was stirred for 5 hours at -78°C. The reaction was quenched with H₂O (10 mL) and the mixture was extracted with EtOAc (2x10 mL) and the combined organic layers were washed with brine (10 mL), were dried over Na₂SO₄, filtered and the solvent evaporated under reduced pressure. The residue was solved in CH₂Cl₂ and was added molecular sieves (18 mg), NMO (29 mg, 0.250 mmol) and a catalytic amount of TPAP and was stirred at room temperature for 16 hours. The reaction was filtered under celite and the residue was purified by chromatography on silica gel (5% EtOAc/Hexane) affording ketone 32 (21 mg, 39% three steps). **Compound 32:** colourless oil, [α]_D^24 = 75.9(c 0.53, CHCl₃), Rr 0.66 (30% EtOAc/Hexane).\(^1\)H NMR (CDCl₃, δ): 8.02 – 7.96 (m, 2H, CH_o-Ph(C1)), 7.63 – 7.57 (m, 1H, CH_p-Ph(C1)), 7.52 – 7.46 (m, 2H, CH_m-Ph(C1)), 7.38 – 7.32 (m, 4H, CH_o,m-Ph(C-6')), 7.31 – 7.26 (s, 1H, CH_p-Ph(C-6')), 4.99 – 4.89 (m, 1H, CH-6'), 4.79 – 4.68 (m, 3H, CH₂-2', CH₂-MOM), 4.20 – 4.07 (m, 1H, CH-4''), 3.57 – 3.45 (m, 1H, CH₂-2'), 3.41 – 3.30 (m, 4H, CH₂-2', CH₃-MOM), 2.35 – 2.24 (m, 1H, CH₂-3'), 2.15 – 2.04 (m, 1H, CH₂-5'), 1.97 – 1.86 (m, 1H, CH₂-5'), 1.75 – 1.65 (m, 1H, CH₂-3').\(^1\)C NMR (CDCl₃, δ): 197.86 (CO), 141.81 (C-Ph(C6')), 136.83 (C-Ph(C1)), 133.33 (CH_p-Ph(C6')), 128.75 (CH_o-Ph(C1)), 128.42 (CH_o-Ph(C6)), 128.22 (CH_m-Ph(C6')), 127.65 (CH_p-Ph(C6')), 126.11 (CH_m-Ph(C1)), 94.47 (CH₂-MOM), 71.98 (CH₂-2'), 70.19 (CH-6'), 69.47 (CH-4'), 55.43 (CH₃-MOM), 41.07 (CH₂-2), 40.04 (CH₂-3').

27. Crystallographic data were collected on a Bruker Smart 1000 CCD diffractometer at CACTI (Universidade de Vigo) at 20ºC using graphite monochromated Mo Kα radiation (λ = 0.71073 Å), and were corrected for Lorentz and polarisation effects. The frames were integrated with the Bruker SAINT software package and the data were corrected for absorption using the program SADABS. The structures were solved by direct methods using the program SHELXS97. All non-hydrogen atoms were refined with anisotropic thermal parameters by full-matrix least-squares calculations on F2 using the program SHELXL97. Hydrogen atoms were inserted at calculated positions and constrained with isotropic thermal parameters. The structural data have been deposited with the Cambridge Crystallographic Data Centre (CCDC) with reference number CCDC 832477.
