**Experimental procedures**

All the solvents and reagents were used commercial without further purification. All the palladium sources, ligands and bases used in the cross-couplings were used commercial (Aldrich, Acros, Strem) and stored under argon in a desiccator. Dry solvents were used commercial (Aldrich, Acros) and stored under argon using Sure/Seal™ or AcroSeal™ technology. TLC Analyses were performed on silica gel coated aluminium plates 60 F254 under UV visualization (254 or 365 nm). Column chromatography was performed using silica gel 60 (230–400 mesh) (Sigma Aldrich) containing ~ 0.1% Ca. Melting points were measured using Kofler hot plate microscope Boetius PHMK 80/2644. NMR Spectra were measured using either Bruker AVANCE III spectrometer operating at 400.13 (\(^1\)H) and 100.12 MHz (\(^{13}\)C) or Bruker Ascend™ spectrometer operating at 500.13 (\(^1\)H) and 125.15 MHz (\(^{13}\)C). Multiplicity of the signals is depicted as s (singlet), d (doublet), t (triplet), quint (quintet), m (multiplet), dd (doublet of doublets), td (triplet of doublets), br (broad signal). Proton NMR spectra in CDCl\(_3\) were calibrated using internal TMS (\(\delta = 0.00\)) and in DMSO-d6 on the middle signal of the solvent multiplet (\(\delta = 2.50\)). Carbon NMR spectra were referenced against the middle signal of the solvent multiplet (\(\delta = 77.23\) for CDCl\(_3\) and 39.51 for DMSO-d6). Measurement of \(^{13}\)C NMR was done in an ordinary way using broadband proton decoupling or by means of APT pulse sequence. Elemental analyses were performed on a Flash EA 2000 CHNS automatic analyser (Thermo Fisher Scientific). HRMS were measured using dried droplet method on a MALDI LTQ Orbitrap XL (Thermo Fisher Scientific) with 2,5-dihydroxybenzoic acid (DHB) or 9-aminoacridine (9-AA) as the matrices for positive or negative mode respectively.

A modified procedure from ref.16 was used. A dried Schlenk flask equipped with a magnetic stirring bar was charged with the starting substrate 4, 6 or 8 (10 mmol). The flask was 3 × evacuated and backfilled with argon. Dry DMF (20 mL) was added via syringe. The apparatus was then cooled to –40 °C (acetone-dry ice bath) and sodium hydride (12 mmol, 1.2 eq.) was added in one portion. The mixture was stirred at –40 °C until foaming ceased (ca 1.5 h). 2-Bromobenzylbromide (12 mmol, 1.2 eq.) was then added in one portion under cooling. The flask was removed from cooling bath and heated under inert to 80 °C for 24 h. After cooling in an ice bath, the reaction was quenched with saturated aq. NH₄Cl (50 mL). Organic layer was diluted with ethyl acetate (125 mL), washed with water (3 × 50 mL) and brine (2 × 50 mL) and dried over anhydrous sodium sulphate. Evaporation to dryness gave crude 9. For purification see details at individual compounds.

**Synthesis of [1,2-a]-fused tricyclic dihydroquinolines 11a–1**

**Method A:** A dried screw-cup vial, equipped with a magnetic stirring bar and septum was charged with substrate 9 (0.5 mmol), Pd$_2$(dba)$_3$ (3.5–5 mol. %), DPPP (7–10 mol. %) and tBuONa (0.6 mmol, 1.2 eq.). The vial was sealed and three-times evacuated and backfilled with argon. Dry toluene (2 mL) was then added via syringe and the mixture was heated to 100 °C for 24–36 h (for exact conditions see Table 3). The mixture was then cooled, diluted with AcOEt and filtered through a plug of Celite®. The filtrate was evaporated to dryness, the residue was suspended in ether (25 mL) and subjected to an ultrasound irradiation. Precipitated impurities were removed by a filtration through Celite®. The pure product 11 was obtained upon evaporation of the filtrate.

**Method B:** A dried screw-cup vial, equipped with a magnetic stirring bar and septum was charged with substrate 9 (0.5 mmol), precatalyst L1 (1.5–2 mol. %) and K$_3$PO$_4$ (1 mmol, 2 eq.). The vial was sealed and three-times evacuated and backfilled with argon. Dry tBuOH (2 mL) was added via syringe and the mixture was heated to 80 °C for 16–24 h (for exact conditions see Table 3). The mixture was then cooled, diluted with AcOEt and filtered through a plug of Celite®. The pure product 11 was obtained upon evaporation of the filtrate.

**Method C:** A dried screw-cup vial (A) equipped with a magnetic stirring bar and septum was charged with substrate 9 (0.5 mmol) and Cs$_2$CO$_3$ (0.7 mmol, 1.4 eq.). Another vial (B) equipped with a magnetic stirring bar and septum was charged with Pd$_2$(dba)$_3$ (22.9 mg, 5 mol.%) and RuPhos (23.3 mg, 10 mol.%). Both the vials were sealed and three-times evacuated and backfilled with argon. Toluene (3 mL) was added via syringe into the vial B. The mixture was then heated to 100 °C for 30 minutes and subsequently transferred into the vial A via syringe. The mixture was then heated to 100 °C for 60 h. The mixture was then cooled, diluted with AcOEt and filtered through a plug of Celite®. The filtrate was evaporated to dryness to give product 11.

X-Ray data

General information

The X-ray data for colorless crystals of 9d, 10a, 12d were obtained at 150 K using Oxford Cryostream low-temperature device on a Nonius Kappa CCD diffractometer with Mo Kα radiation (λ = 0.71073 Å), a graphite monochromator, and the φ and χ scan mode. Data reductions were performed with DENZO-SMN. The absorption was corrected by integration methods. Structures were solved by direct methods (Sir92) and refined by full matrix least-square based on F² (SHELXL97). Hydrogen atoms were mostly localized on a difference Fourier map, however to ensure uniformity of treatment of crystal, all hydrogen were recalculated into idealized positions (riding model) and assigned temperature factors H iso(H) = 1.2 U eq (pivot atom) or of 1.5U eq (methyl). H atoms in methyl, methylene, and hydrogen atoms in aromatic rings were placed with C–H distances of 0.96, 0.97 and 0.93 Å and 0.86 Å for N–H bonds.

Crystal structures

The structure of three compounds predicted on the basis of physico-chemical and spectral measurements was unambiguously proven by X-ray diffraction techniques on single-crystalline material. In both 9d and 10a (see Figs. S1 and S2), the structures are influenced by rather strong in-plane intramolecular H-bonds of NH to the carbonyl group, which has in 9d also a centrosymmetric counterpart making thus a dimer in the solid state. This particular dimeric arrangement is most probably prevented in the structure of 10a by the presence of bulky and highly flexible benzyl substituents. The presence of C=–C bond is seen from interatomic distances of C8–C11 in 9d and C8–C10 in 10a (see Fig. S2 captions), where the later one is slightly longer due to its connection to more strained six-membered ring in combination with more steric hindrance at C8 atom. The only reported structures of related pyrrolidin-2-ylidenes and piperidin-2-ylidenes have very similar arrangements and parameters of interest.
**Figure S1.** The molecular structure (ORTEP view, 50% probability level) of 9d, the second independent molecule is omitted for clarity, appropriate parameters are given in parentheses. Selected interatomic distances [Å] and angles [°]: N1–C11 1.333(3) (1.327(3)), N1–C12 1.454(3) (1.455(3)), C8–C11 1.386(4) (1.385(4)), C8–C9 1.432(4) (1.429(4)), C7–C8 1.514(4) (1.509(4)), O1–C9 1.251(3) (1.254(3)); C11–N1–C12 115.6(2) (116.1(2)); interplanar angle: ring (N1–C11–C14–C13–C12) vs. ring (C1–C2–C3–C4–C5–C6) 67.82(1) (80.85(2)). The crystal was obtained upon slow evaporation of the solution of 9d in acetonitrile.
**FIGURE S2.** The molecular structure (ORTEP view, 50% probability level) of 10a, disordered part of phenyl ring is omitted for clarity. Selected interatomic distances [Å] and angles [°]: N1–C11 1.465(5), N1–C10 1.322(5), C8–C10 1.405(6), C9–C8 1.422(6), C15–C9 1.543(6), O1–C9 1.252(5); C10–N1–C11 126.7(4). The crystal was obtained upon slow cooling and subsequent gradual evaporation of the hot ethanolic solution of 10a.

In 12d (Fig. S3), the expected parameters of interatomic separations as well as the bonding angles were found. On the other hand there is no mention about similar structure of such kind in the literature, and only modestly related structures of azepines were determined. The seven membered ring in 12d is flapped below the plane of the aromatic system interacting weakly via C-H···O connections with perchlorate anion.
**FIGURE S3.** The molecular structure (ORTEP view, 50% probability level) of 12d. Selected interatomic distances [Å] and angles [°]: N1–C11 1.342(2), N1–C12 1.498(2), N1–C1 1.393(2), C1–C2 1.414(2), C7–C2 1.404(2), C8–C7 1.367(2), C8–C11 1.413(2), C8–C9 1.500(2), O1–C9 1.198(2); C11–N1–C1 122.38(13); interplanar angle: aromatic system vs. ester group 39.54(2). The crystal was obtained upon gradual cooling and subsequent slow evaporation of the solution of 12d in aqueous methanol (4:1).

NMR Data

NMR Spectra were measured using either Bruker AVANCE III spectrometer operating at 400 MHz (¹H) and 100 MHz (¹³C) or Bruker Ascend™ operating at 500 MHz (¹H) and 125 MHz (¹³C). Proton NMR spectra in CDCl₃ were calibrated using internal TMS (δ = 0.00) and in DMSO-d6 on the middle signal of the solvent multiplet (δ = 2.50). Carbon NMR spectra were referenced against the middle signal of the solvent multiplet (δ = 77.26 for CDCl₃ and 39.51 for DMSO-d6). Measurement of ¹³C NMR was done using composite pulse proton decoupling in an ordinary way or APT pulse sequence.
