### Abstract

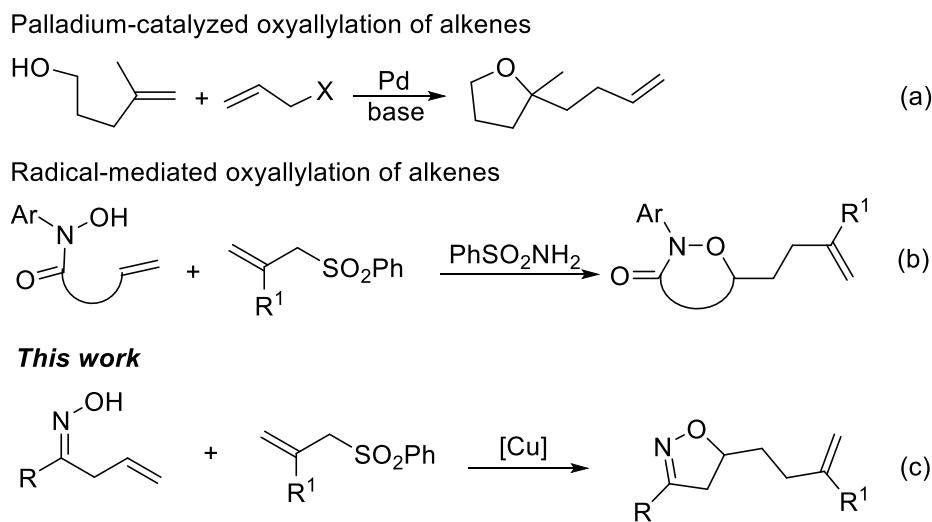

A radical-mediated approach to alkene oxyallylation using allylic oximes is described. The reaction proceeds under copper-catalytic redox-neutral conditions and tolerates various functional groups. This protocol thus enables the synthesis of structurally valuable isoxazolines and the introduction of a versatile olefin motif in a single step.

**Keywords:** allylic oximes, copper-catalytic, oxyallylation, isoxazolines, allyl sulfones

## Introduction

The direct difunctionalization of alkenes, a valuable and readily available feedstock, represents one of the most effective strategies for increasing molecular complexity in synthetic organic chemistry.<sup>1-16</sup> Among them, the oxyallylation of alkenes is a particularly useful reactions, because the alkenes motif in the resulting products offer rich possibilities for synthetic manipulations. Despite significant advances in the oxyfunctionalization of alkenes,<sup>17-26</sup> oxyallylation of alkenes have been little explored. France and co-workers developed the palladium-catalyzed oxyallylation of unactivated alkenes using phenols, alcohol and carboxylic acid as the nucleophiles (Scheme 1a).<sup>27</sup> However, monosubstituted alkene are not tolerated under the given reaction conditions, because of the  $\beta$ -hydride elimination of the putative  $\sigma$ -alkyl Pd(II) intermediate. Alternatively, Alexanian and co-workers demonstrated the radical-mediated oxyallylation of alkenes with allyl sulfones using hydroxamic acids as the radical precursor with the assistance of PhSO<sub>2</sub>NH<sub>2</sub> (Scheme 1b).<sup>28</sup> Although highly practical, the types of oxygen-centered radicals remain limited. Encouraged by the works of Han,<sup>29,30</sup> Wang,<sup>31</sup> and our group<sup>32</sup> on the copper-catalyzed iminoxyl radical-mediated oxyfunctionalization of alkenes, we envisioned that iminoxyl radical may also be involved in the oxyallylation with allyl sulfones. Herein, we describe more convenient method, which has led to the construction of useful isoxazolines<sup>33-43</sup> and the installation of versatile alkenyl groups in one transformation. It is expected that the resulting C=C bond will serve as a useful precursor for obtaining other isoxazoline-containing compounds.

**Scheme 1.** Oxyallylation of alkenes.

## Results and Discussion

The initial experiments were carried out with allylic oxime **1a** and allyl sulfone **2a** as the model substrates (Table 1 and S1). When the standard reaction conditions developed by our previous work revealed that using (Cu(OTf)<sub>2</sub>, 1,10-phen and Na<sub>2</sub>CO<sub>3</sub> were used as catalyst, ligand and base respectively in MeCN at 80 °C ), the desired isooxazoline **3a** was produced in 57% NMR yield. Inspired by these result, various reaction parameters were changed to explore the sensitivity of this reaction. Cu(II) catalysts were generally more effective than Cu(I) sources (entries 1-3 vs entries 4-6). Bpy was also effective ligand (entry 7), but the reaction yield diminished with TMEDA (entry 8). Other solvents, such as DCE, EtOH, toluene, THF and DMF uniformly less

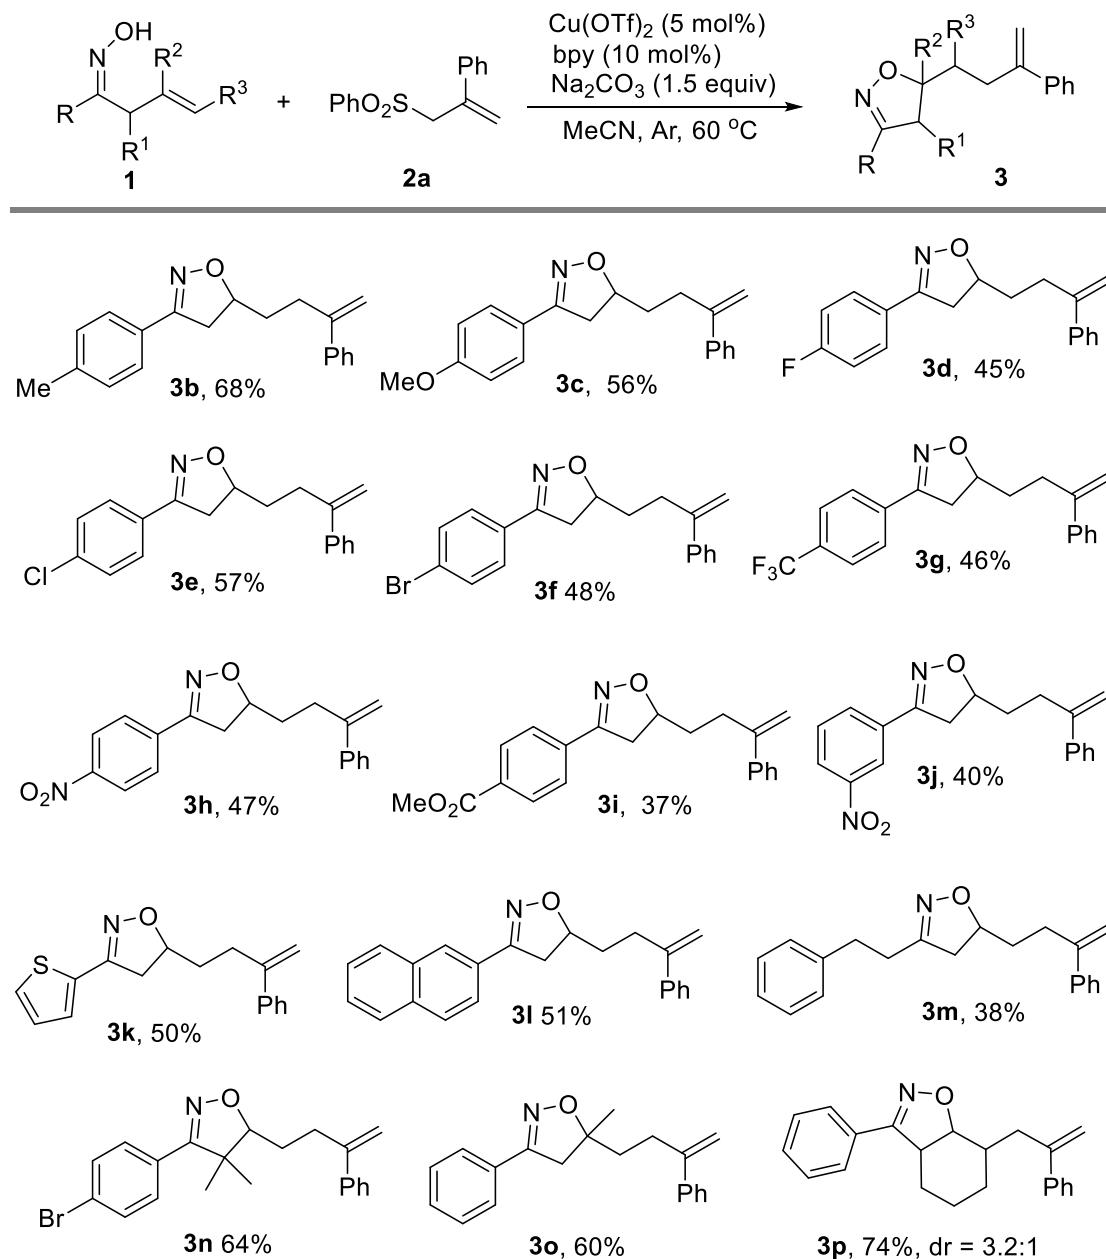

effective than MeCN (entries 9-13). Importantly, the loading of **2a** had significant effect on the reactions. Increasing the loading to 3 equiv provides **3a** in 84% NMR yield (entry 14). It is noteworthy that the remaining **2a** could be recovered quantitatively. Finally, the reaction temperature could be reduced to 60 °C without the loss the reaction efficiency (entry 15). In the absence of Cu(OTf)2 and base, the reactions could hardly occur (entries 16-17), while control experiment lacking ligand was less effective (entry 18).

<sup>a</sup>Reaction conditions: **1a** (0.10 mmol), **2a** (0.15 mmol), copper catalyst (0.005 mmol), Ligand (0.01 mmol), base (0.15 mmol), solvent (1 mL), at 80 °C under argon. <sup>b</sup>HPLC yields using naphthalene as an internal standard. <sup>c</sup>Isolated yield. <sup>d</sup>0.30 mmol of **2a** was used. <sup>e</sup>60 °C. <sup>f</sup>without base.

With the optimized conditions in hand, we next tested the reaction scope with respect to the allylic oximes, keeping allyl sulfone **2a** as the substrate (Scheme 2). Allylic oximes bearing various electronically different substituents (methyl, methoxyl, fluoro, chloro, bromo, trifluoromethyl, nitro, and ester groups) proved to be suitable substrates and provided products **3b-j** in moderate yields. In addition, naphthyl and thien-2-yl oxime were converted smoothly to the corresponding products (**3k-l**). Importantly, aliphatic oxime, such as phenethyl oxime was suitable substrate, delivering the isoxazoline (**3m**) was useful yield. Then, oximes with substituted allylic group were tested. Oxime with double-methyl substituton at R<sup>1</sup> position (**3n**, 64% yield) showed higher reactivity than unsubstituted one (**3f**, 48% yield). Moreover, oxime with steric 1,1-disubstituted alkene group was converted smoothly to the corresponding product (**3o**, 60% yield). Finally, oxime of phenyl cyclohex-2-enyl methanone, having a cyclic allyl unit also proved to be a reactive substrate, transforming into the product **3p** in 74% yield.

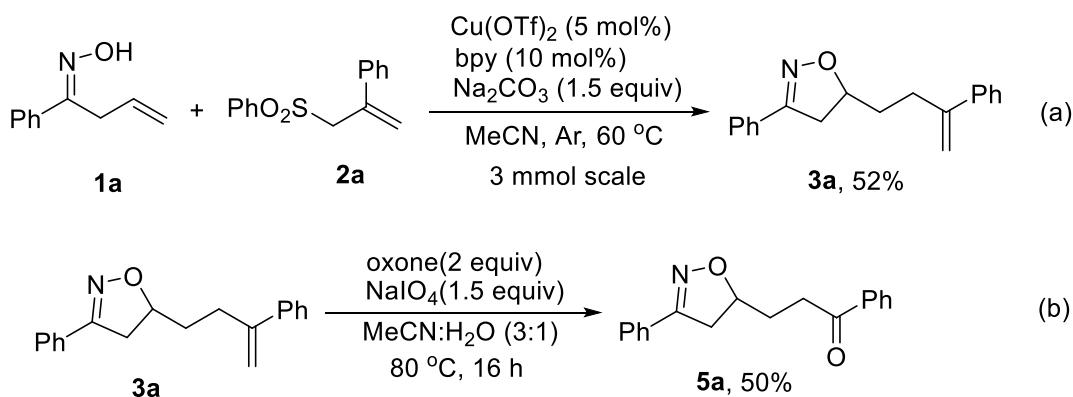

**Scheme 2.** Substrate scope of allylic oximes. <sup>a</sup>Reaction conditions: 1 (0.20 mmol), 2a (0.60 mmol),  $\text{Cu}(\text{OTf})_2$  (5 mol%),  $\text{bpy}$  (10 mol%) and  $\text{Na}_2\text{CO}_3$  (0.30 mmol) in  $\text{MeCN}$  (2.0 mL) at  $60^\circ\text{C}$  for 12 h, under argon. <sup>b</sup>Isolated yields.

Next, we surveyed various allyl sulfones. As summarized in Scheme 3, when the phenyl group in **1a** was replaced by ester group, isoxazoline with useful  $\alpha,\beta$ -unsaturated ester groups **4a-c** were prepared in 51-62% yields. Similarly, cyano and benzoyl substituted allyl sulfones were successfully engaged in the cyclization to yield products **4d-e** in 52% and 32% yields, respectively.

**Scheme 3.** Substrate scope of allyl sulfones. <sup>a</sup>Reaction conditions: **1a** (0.20 mmol), **2a** (0.60 mmol), Cu(OTf)<sub>2</sub> (5 mol%), bpy (10 mol%) and Na<sub>2</sub>CO<sub>3</sub> (0.30 mmol) in MeCN (2 mL) at 60 °C for 12 h, under argon. <sup>b</sup>Isolated yields.

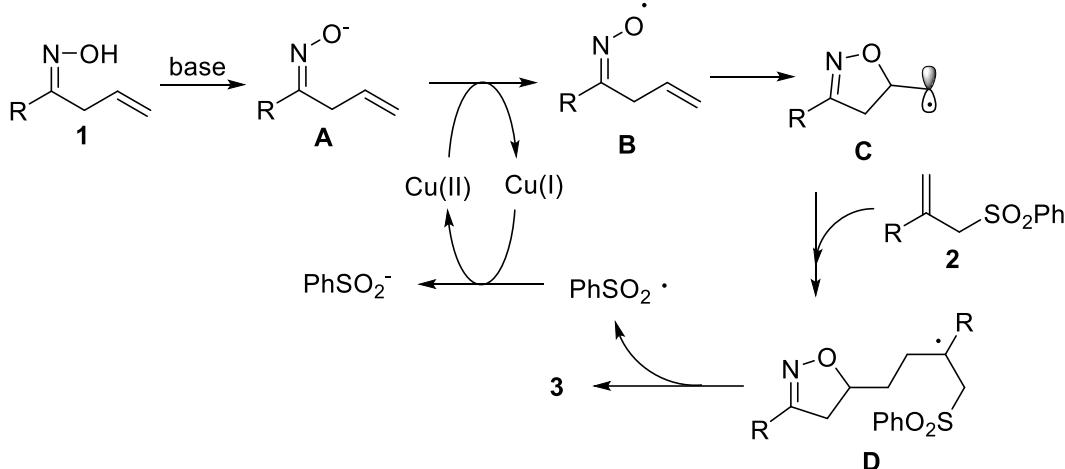

To show practicality of this protocol, we scaled up the reaction to 3 mmol, and the isoxazoline **3a** was isolated in 52% yield (0.43 g) (Scheme 4a). The synthetic utility of the alkene-containing isoxazoline was exemplified by the oxidative cleavage of C=C double bond<sup>44</sup> into isoxazoline with ketone side chain. Treatment of **3a** with 2 equiv of oxone and 1.5 equiv of NaIO<sub>4</sub> under 80 °C led to the isolation of **5a** in 50% yield (Scheme 4b).

**Scheme 4.** Gram scale reaction and product derivatization.

According to the above experimental results and previous reports, a plausible mechanism is proposed (Scheme 5). Firstly, iminooxyl anion **A**, formed by deprotonation of

substrates **1** were SET oxidized by Cu(II), to generate the iminoxyl radical **B**.<sup>32</sup> Then, iminoxyl radical **B** undergoes 5-exo-trig radical cyclization, delivering the carbon-centered radical intermediate **C**. The addition of the radical **C** onto the C=C bond of allyl sulfone **2** followed by desulfonation leads to the product **3** and a sulfonyl radical.<sup>45,46</sup> Finally, SET reduction of sulfonyl radical by Cu(I) forms the benzenesulfinic acid anion with the concomitant regeneration of Cu(II).

**Scheme 5.** Proposed mechanism.

## Conclusions

We have developed an efficient copper-catalyzed radical oxyallylation of alkenes with allylic sulfones using oximes as the oxygen-centered radical precursor. This new method provided a practical approach to isoxazolines containing an alkene moiety in moderate to good yields, which may act as a versatile platform allowing further downstream diversification.

## Experimental Section

**General.** Unless stated otherwise, all reactions were carried out under an argon atmosphere. All commercial reagents were used without additional purification. Flash chromatography was carried out with silica gel (200–300 mesh). Melting points were determined without correction on a digital melting-point apparatus. <sup>1</sup>H NMR, <sup>13</sup>C NMR and <sup>19</sup>F NMR spectra were recorded at 500 (600) MHz, 125 (150) MHz and 400 MHz spectrometers in CDCl<sub>3</sub> using tetramethylsilane (TMS) as internal standard, respectively. High resolution mass spectra (HRMS) were obtained by the ESI ionization sources.

**Experimental procedures and characterization of products.** To a dried reaction tube was added allyl oxime **1** (0.20 mmol), **2** (0.60 mmol), Cu(OTf)<sub>2</sub> (5 mol%), bpy (10 mol%), Na<sub>2</sub>CO<sub>3</sub> (0.30 mmol). The tube was evacuated and backfilled with argon (three times). Then, anhydrous MeCN (2.0 mL) was injected into the tube by syringe. The solution was kept at 60 °C for 12 h. The reaction mixture was partitioned with EtOAc and water. The organic layer was separated and washed with brine, dried over anhydrous Na<sub>2</sub>SO<sub>4</sub> and concentrated under

reduced pressure. The crude mixture was purified by silica gel column chromatography (PE/EA 30:1, v/v) to give the corresponding product **3 or 4**.
